Preface

Foreword

This book tries to give you a guide to start your own experiments into the wonderful world of Wireshark development.

Developers who are new to Wireshark often have a hard time getting their development environment up and running. This is especially true for Win32 developers, as a lot of the tools and methods used when building Wireshark are much more common in the UNIX world than on Win32.

The first part of this book will describe how to set up the environment needed to develop Wireshark.

The second part of this book will describe how to change the Wireshark source code.

We hope that you find this book useful, and look forward to your comments.

Who should read this document?

The intended audience of this book is anyone going into the development of Wireshark.

This book is not intended to explain the usage of Wireshark in general. Please refer the Wireshark User's Guide about Wireshark usage.

By reading this book, you will learn how to develop Wireshark. It will hopefully guide you around some common problems that frequently appear for new (and sometimes even advanced) developers of Wireshark.

Acknowledgements

The authors would like to thank the whole Wireshark team for their assistance. In particular, the authors would like to thank:

- Gerald Combs, for initiating the Wireshark project.
- Guy Harris, for many helpful hints and his effort in maintaining the various contributions on the mailing lists.
- Frank Singleton from whose README.idl2wrs idl2wrs: Creating dissectors from CORBA IDL files is derived.

The authors would also like to thank the following people for their helpful feedback on this document:
And of course a big thank you to the many, many contributors of the Wireshark development community!

**About this document**

This book was developed by Ulf Lamping, updated for VS2013 by Graham Bloice, and updated for later versions of Visual Studio by various contributors.

It is written in AsciiDoc.

**Where to get the latest copy of this document?**

The latest copy of this documentation can always be found at {wireshark-docs-url}wsdg_html_chunked/.

**Providing feedback about this document**

Should you have any feedback about this document, please send it to the authors through wireshark-dev[AT]wireshark.org.

**Typographic Conventions**

The following table shows the typographic conventions that are used in this guide.

*Table 1. Typographic Conventions*

<table>
<thead>
<tr>
<th>Style</th>
<th>Description</th>
<th>Example</th>
</tr>

Admonitions

Important and notable items are marked as follows:

**WARNING**

This is a warning
You should pay attention to a warning, otherwise data loss might occur.

**NOTE**

This is a note
A note will point you to common mistakes and things that might not be obvious.

**TIP**

This is a tip
Tips are helpful for your everyday work using Wireshark.

Shell Prompt and Source Code Examples

* Bourne shell, normal user

```bash
$ # This is a comment
$ git config --global log.abbrevcommit true
```

* Bourne shell, root user

```bash
# # This is a comment
# ninja install
```

* Command Prompt (cmd.exe)

```cmd
>rem This is a comment
>cd C:\Development
```

* PowerShell

```powershell
PS$># This is a comment
PS$>choco list -l
```
#include "config.h"

/* This method dissects foos */
static int
dissect_foo_message(tvbuff_t *tvb, packet_info *pinfo _U_, proto_tree *tree _U_, void *
data _U_)
{
  /* TODO: implement your dissecting code */
  return tvb_captured_length(tvb);
}
Wireshark Build Environment

The first part describes how to set up the tools, libraries and source needed to generate Wireshark and how to do some typical development tasks.
Introduction

This chapter will provide you with information about Wireshark development in general.

What is Wireshark?

Well, if you want to start Wireshark development, you might already know what Wireshark is doing. If not, please have a look at the Wireshark User's Guide, which will provide a lot of general information about it.

Supported Platforms

Wireshark currently runs on most UNIX-like platforms and various Windows platforms. It requires Qt, GLib, libpcap and some other libraries in order to run.

As Wireshark is developed in a platform independent way and uses libraries (such as the Qt GUI library) which are available for many different platforms, it's thus available on a wide variety of platforms.

If a binary package is not available for your platform, you should download the source and try to build it. Please report your experiences to wireshark-dev[AT]wireshark.org.

Binary packages are available for the following platforms along with many others:

Unix and Unix-like platforms

• Apple macOS
• FreeBSD
• HP-UX
• IBM AIX
• NetBSD
• OpenBSD
• Oracle Solaris

Linux

• Debian GNU/Linux
• Ubuntu
• Fedora
• Gentoo Linux
• IBM S/390 Linux (Red Hat)
• Mandrake Linux
• PLD Linux
• Red Hat Linux
• Rock Linux
• Slackware Linux
• Suse Linux

**Microsoft Windows**

Wireshark supports Windows natively via the [Windows API](https://www.wireshark.org/about.html#authors). Note that in this documentation and elsewhere we tend to use the terms “Win32”, “Win”, and “Windows” interchangeably to refer to the Windows API. Wireshark runs on and can be compiled on the following platforms:

• Windows 10 / Windows Server 2016
• Windows 8.1 / Windows Server 2012 R2
• Windows 8 / Windows Server 2012
• Windows 7 / Windows Server 2008 R2

Development on Windows Vista, Server 2008, and older versions may be possible but is not supported.

**Development and maintenance of Wireshark**

Wireshark was initially developed by Gerald Combs. Ongoing development and maintenance of Wireshark is handled by the Wireshark core developers, a loose group of individuals who fix bugs and provide new functionality.

There have also been a large number of people who have contributed protocol dissectors and other improvements to Wireshark, and it is expected that this will continue. You can find a list of the people who have contributed code to Wireshark by checking the About dialog box of Wireshark, or have a look at the [https://www.wireshark.org/about.html#authors](https://www.wireshark.org/about.html#authors) page on the Wireshark web site.

The communication between the developers is usually done through the developer mailing list, which can be joined by anyone interested in the development activities. At the time this document was written, more than 500 persons were subscribed to this mailing list!

It is strongly recommended to join the developer mailing list, if you are going to do any Wireshark development. See [Mailing Lists](https://www.wireshark.org/about.html#authors) about the different Wireshark mailing lists available.
Programming languages used

Most of Wireshark is implemented in plain ANSI C. A notable exception is the code in `ui/qt`, which is written in C++.

The typical task for a new Wireshark developer is to extend an existing, or write a new dissector for a specific network protocol. As (almost) any dissector is written in plain old ANSI C, a good knowledge about ANSI C will be sufficient for Wireshark development in almost any case.

So unless you are going to change the build process of Wireshark itself, you won't come in touch with any other programming language than ANSI C (such as Perl or Python, which are used only in the Wireshark build process).

Beside the usual tools for developing a program in C (compiler, make, ...), the build process uses some additional helper tools (Perl, Python, Sed, ...), which are needed for the build process when Wireshark is to be build and installed from the released source packages. If Wireshark is installed from a binary package, none of these helper tools are needed on the target system.

Open Source Software

Wireshark is an open source software (OSS) project, and is released under the GNU General Public License (GPL). You can freely use Wireshark on any number of computers you like, without worrying about license keys or fees or such. In addition, all source code is freely available under the GPL. Because of that, it is very easy for people to add new protocols to Wireshark, either as plugins, or built into the source, and they often do!

You are welcome to modify Wireshark to suit your own needs, and it would be appreciated if you contribute your improvements back to the Wireshark community.

You gain three benefits by contributing your improvements back to the community:

- Other people who find your contributions useful will appreciate them, and you will know that you have helped people in the same way that the developers of Wireshark have helped you and other people.
- The developers of Wireshark might improve your changes even more, as there's always room for improvement. Or they may implement some advanced things on top of your code, which can be useful for yourself too.
- The maintainers and developers of Wireshark will maintain your code as well, fixing it when API changes or other changes are made, and generally keeping it in tune with what is happening with Wireshark. So if Wireshark is updated (which is done often), you can get a new Wireshark version from the website and your changes will already be included without any effort for you.

The Wireshark source code and binary packages for some platforms are all available on the download page of the Wireshark website: [https://www.wireshark.org/download.html](https://www.wireshark.org/download.html).
Releases and distributions

The officially released files can be found at https://www.wireshark.org/download.html. A new Wireshark version is released after significant changes compared to the last release are completed or a serious security issue is encountered. The typical release schedule is about every 4-8 weeks (although this may vary). There are two kinds of distributions: binary and source; both have their advantages and disadvantages.

Binary distributions

Binary distributions are usually easy to install (as simply starting the appropriate file is usually the only thing to do). They are available for the following systems:

- Windows (.exe file). The typical Windows end user is used to getting a setup.exe file which will install all the required things for him.
- Win32 PAF (.paf.exe file). Another Windows end user method is to get a portable application file which will install all the required things for him.
- Debian (.deb file). A user of a Debian Package Manager (DPKG) based system obtains a .deb file from which the package manager checks the dependencies and installs the software.
- Red Hat (.rpm file). A user of a RPM Package Manager (RPM) based system obtains an .rpm file from which the package manager checks the dependencies and installs the software.
- macOS (.dmg file). The typical macOS end user is used to getting a .dmg file which will install all the required things for him.
- Solaris. A Solaris user obtains a file from which the package manager (PKG) checks the dependencies and installs the software.

However, if you want to start developing with Wireshark, the binary distributions won't be too helpful, as you need the source files, of course.

For details about how to build these binary distributions yourself, e.g. if you need a distribution for a special audience, see Binary Packaging.

Source code distributions

It's still common for developers for UNIX-like platforms to give the end user a source tarball and let the user compile it on their target machine (configure make make install). However, for different UNIX and UNIX-like systems, such as Linux distributions, it's becoming more common to release binary packages (e.g., .deb or .rpm files) these days.

You should use the released sources if you want to build Wireshark from source on your platform for productive use. However, if you going to develop changes to the Wireshark sources, it might be better to use the latest Git sources. For details about the different ways to get the Wireshark source code see Obtain the Wireshark sources.
Before building Wireshark from a source distribution, make sure you have all the tools and libraries required to build. The following chapters will describe the required tools and libraries in detail.

**Automated Builds (Buildbot)**

The Wireshark Buildbot automatically rebuilds Wireshark on every change of the source code repository and indicates problematic changes. This frees the developers from repeating (and annoying) work, so time can be spent on more interesting tasks.

**Advantages**

- Recognizing (cross platform) build problems - early. Compilation problems can be narrowed down to a few commits, making a fix much easier.

- "Health status" overview of the sources. A quick look at: https://buildbot.wireshark.org/wireshark-master/ gives a good "feeling" if the sources are currently "well". On the other hand, if all is "red", an update of a personal source tree might better be done later ...

- "Up to date" binary packages are available. After a change was committed to the repository, a binary package / installer is usually available within a few hours at: https://www.wireshark.org/download/automated/. This can be quite helpful, e.g. a bug reporter can easily verify a bugfix by installing a recent build.

- Automated regression tests. In particular, the fuzz tests often indicate "real life" problems that are otherwise hard to find.

**What does the Buildbot do?**

The Buildbot will do the following (to a different degree on the different platforms):

- Check out from the source repository

- Build

- Create binary packages and installers

- Create source packages and run distribution checks

- Run regression tests

Each step is represented at the status page by a rectangle, green if it succeeded or red if it failed. Most steps provide a link to the corresponding console logfile, to get additional information.

The Buildbot runs on a platform collection that represents the different "platform specialties" quite well:

- Windows Server 2016 x86-64 (Win64, little endian, Visual Studio 2017)
• Ubuntu 18.04 x86-64 (Linux, little endian, gcc, Clang)
• macOS 10.14 x86-64 (BSD, little endian, Clang)

and two buildslaves that run static code analysis to help spot coding issues:
• Visual Studio Code Analysis (Win64, little endian, VS 2017)
• Clang Code Analysis (Linux, little endian, Clang)

Each platform is represented at the status page by a single column, the most recent entries are at the top.

**Reporting problems and getting help**

If you have problems, or need help with Wireshark, there are several places that may be of interest to you (well, beside this guide of course).

**Website**

You will find lots of useful information on the Wireshark homepage at [https://www.wireshark.org/](https://www.wireshark.org/).

**Wiki**

The Wireshark Wiki at [https://wiki.wireshark.org/](https://wiki.wireshark.org/) provides a wide range of information related to Wireshark and packet capturing in general. You will find a lot of information not part of this developer’s guide. For example, there is an explanation how to capture on a switched network, an ongoing effort to build a protocol reference and a lot more.

And best of all, if you would like to contribute your knowledge on a specific topic (maybe a network protocol you know well), you can edit the Wiki pages by simply using your webbrowser.

**FAQ**

The "Frequently Asked Questions" will list often asked questions and the corresponding answers.

Before sending any mail to the mailing lists below, be sure to read the FAQ, as it will often answer any questions you might have. This will save yourself and others a lot of time. Keep in mind that a lot of people are subscribed to the mailing lists.

You will find the FAQ inside Wireshark by clicking the menu item Help/Contents and selecting the FAQ page in the upcoming dialog.

An online version is available at the Wireshark website: [https://www.wireshark.org/faq.html](https://www.wireshark.org/faq.html). You might prefer this online version as it’s typically more up to date and the HTML format is easier to use.
Other sources

If you don’t find the information you need inside this book, there are various other sources of information:

- The file `doc/README.developer` and all the other README.xxx files in the source code. These are various documentation files on different topics
  
  **NOTE**

  Read the README

  `README.developer` is packed full with all kinds of details relevant to the developer of Wireshark source code. Its companion file `README.dissector` advises you around common pitfalls, shows you basic layout of dissector code, shows details of the APIs available to the dissector developer, etc.

- The Wireshark source code
- Tool documentation of the various tools used (e.g. manpages of sed, gcc, etc.)
- The different mailing lists. See Mailing Lists

Q&A Site

The Wireshark Q&A site at https://ask.wireshark.org/ offers a resource where questions and answers come together. You have the option to search what questions were asked before and what answers were given by people who knew about the issue. Answers are graded, so you can pick out the best ones easily. If your issue isn’t discussed before you can post one yourself.

Mailing Lists

There are several mailing lists available on specific Wireshark topics:

**wireshark-announce**

This mailing list will inform you about new program releases, which usually appear about every 4-8 weeks.

**wireshark-users**

This list is for users of Wireshark. People post questions about building and using Wireshark, others (hopefully) provide answers.

**wireshark-dev**

This list is for Wireshark developers. People post questions about the development of Wireshark, others (hopefully) provide answers. If you want to start developing a protocol dissector, join this list.

**wireshark-bugs**

This list is for Wireshark developers. Every time a change to the bug database occurs, a mail to
This mailing list is generated. If you want to be notified about all the changes to the bug database, join this list. Details about the bug database can be found in Bug database (Bugzilla).

**wireshark-commits**

This list is for Wireshark developers. Every time a change to the Git repository is checked in, a mail to this mailing list is generated. If you want to be notified about all the changes to the Git repository, join this list. Details about the Git repository can be found in The Wireshark Git repository.

You can subscribe to each of these lists from the Wireshark web site: [https://www.wireshark.org/lists/](https://www.wireshark.org/lists/). From there, you can choose which mailing list you want to subscribe to by clicking on the Subscribe/Unsubscribe/Options button under the title of the relevant list. The links to the archives are included on that page as well.

**TIP**

The archives are searchable

You can search in the list archives to see if someone previously asked the same question and maybe already got an answer. That way you don’t have to wait until someone answers your question.

**Bug database (Bugzilla)**

The Wireshark community collects bug reports in a Bugzilla database at [https://bugs.wireshark.org/](https://bugs.wireshark.org/). This database is filled with manually filed bug reports, usually after some discussion on wireshark-dev, and automatic bug reports from the Buildbot tools.

**Reporting Problems**

**NOTE**

Test with the latest version

Before reporting any problems, please make sure you have installed the latest version of Wireshark. Reports on older maintenance releases are usually met with an upgrade request.

If you report problems, provide as much information as possible. In general, just think about what you would need to find that problem, if someone else sends you such a problem report. Also keep in mind that people compile/run Wireshark on a lot of different platforms.

When reporting problems with Wireshark, it is helpful if you supply the following information:

1. The version number of Wireshark and the dependent libraries linked with it, e.g. Qt, GLib, etc. You can obtain this with the command `wireshark -v`.
2. Information about the platform you run Wireshark on.
3. A detailed description of your problem.
4. If you get an error/warning message, copy the text of that message (and also a few lines before and after it, if there are some), so others may find the build step where things go wrong. Please
don’t give something like: "I get a warning when compiling x" as this won’t give any direction to look at.

**NOTE**

*Don’t send large files*

Do not send large files (>100KB) to the mailing lists, just place a note that further data is available on request. Large files will only annoy a lot of people on the list who are not interested in your specific problem. If required, you will be asked for further data by the persons who really can help you.

**WARNING**

*Don’t send confidential information*

If you send captured data to the mailing lists, or add it to your bug report, be sure it doesn’t contain any sensitive or confidential information, such as passwords. Visibility of such files can be limited to certain groups in the Bugzilla database though.

### Reporting Crashes on UNIX-like platforms

When reporting crashes with Wireshark, it is helpful if you supply the traceback information (besides the information mentioned in Reporting Problems).

You can obtain this traceback information with the following commands:

```
$ gdb `whereis wireshark | cut -f2 -d: | cut -d' ' -f2` core >& bt.txt
backtrace
^D
$
```

**Using GDB**

Type the characters in the first line verbatim. Those are back-tics there.

`backtrace` is a `gdb` command. You should enter it verbatim after the first line shown above, but it will not be echoed. The `^D` (Control-D, that is, press the Control key and the D key together) will cause `gdb` to exit. This will leave you with a file called `bt.txt` in the current directory. Include the file with your bug report.

If you do not have `gdb` available, you will have to check out your operating system’s debugger.

You should mail the traceback to `wireshark-dev[AT]wireshark.org` or attach it to your bug report.

### Reporting Crashes on Windows platforms

You can download Windows debugging symbol files (.pdb) from the following locations:
• 32-bit Windows: https://www.wireshark.org/download/win32/all-versions/
• 64-bit Windows: https://www.wireshark.org/download/win64/all-versions/

Files are named "Wireshark-pdb-winbits-x.y.z.zip" to match their corresponding "Wireshark-winbits-x.y.z.exe" installer packages.
Quick Setup

UNIX: Installation

All the tools required are usually installed on a UNIX developer machine.

If a tool is not already installed on your system, you can usually install it using the package in your distribution: aptitude, yum, Synaptic, etc.

If an install package is not available or you have a reason not to use it (maybe because it's simply too old), you can install that tool from source code. The following sections will provide you with the webpage addresses where you can get these sources.

Win32/64: Step-by-Step Guide

A quick setup guide for Win32 and Win64 with recommended configuration.

WARNING

Unless you know exactly what you are doing, you should strictly follow the recommendations below. They are known to work and if the build breaks, please re-read this guide carefully.

Known traps are:

1. Not using the correct (x86 or x64) version of the Visual Studio command prompt.
2. Not copying/downloading the correct version of vcredist_xYY.exe.

Recommended: Install Chocolatey

Chocolatey is a native package manager for Windows. There are packages for most of the software listed below. Along with traditional Windows packages it supports the Python Package Index.

Chocolatey tends to install packages into its own path (%ChocolateyInstall%), although packages are free to use their own preferences (Python for example is installed to C:\Python37). You can install Chocolatey packages using the command choco install (or its shorthand, cinst), e.g.

> rem Flex and Bison are required.
> choco install -y winflexbison
> rem Git, CMake, Perl, Python, etc are also required, but can be installed
> rem via their respective installation packages.
> choco install -y git cmake strawberryperl python3
Install Microsoft Visual Studio

Download and install “Microsoft Visual Studio 2019 Community Edition.” This is a small utility that downloads all the other required parts (which are quite large).

Check the checkbox for “Desktop development with C++” and then uncheck all the optional components other than the “VC++ 2019” item with the “latest ... tools”, the “Windows 10 SDK”, and the “Visual C++ tools for CMake” (unless you want to use them for purposes other than Wireshark).

You can use Chocolatey to install Visual Studio, to correctly configure the installation, copy the deployment XML file msvc2015AdminDeployment.xml from the source code tools directory and pass the path the file to the chocolatey install command:

```bash
PS$>choco install -y VisualStudio2015Community --timeout 0 -package-parameters "--AdminFile path\to\msvc2015AdminDeployment.xml"
```

You can use other Microsoft C compiler variants, but VS2019 is used to build the development releases and is the preferred option. It's possible to compile Wireshark with a wide range of Microsoft C compiler variants. For details see Microsoft compiler toolchain (Windows native).

You may have to do this as Administrator.

Compiling with gcc or Clang is not recommended and will certainly not work (at least not without a lot of advanced tweaking). For further details on this topic, see GNU Compiler Toolchain (UNIX And UNIX-like Platforms). This may change in future as releases of Visual Studio add more cross-platform support.

Why is this recommended? While this is a huge download, the Community Editions of Visual Studio are free (as in beer) and include the Visual Studio integrated debugger. Visual Studio 2019 is also used to create official Wireshark builds, so it will likely have fewer development-related problems.

Install Qt

The main Wireshark application uses the Qt windowing toolkit. To install Qt, go to the “Download Qt” page, select “Go open source”, download the Qt Online Installer for Windows from the Qt Project and select, for the desired Qt version, a component that matches your target system and compiler. For example, at the time of this writing the Qt 5.12.1 “msvc2017 64-bit” component is used to build the official 64-bit packages. The “Qt Debug Information Files” component contains PDB files which can be used for debugging. You can deselect all of the other the components such as “Qt Charts” or “Android xxxx” as they aren't required.

Note that installation of separate Qt components are required for 32 bit and 64 bit builds, e.g. “msvc2017 32-bit” and “msvc2017 64-bit”. The environment variable QT5_BASE_DIR should be set as appropriate for your environment and should point to the Qt directory that contains the bin directory, e.g. C:\Qt\5.12.5\msvc2017_64
The Qt maintenance tool (C:\Qt\MaintenanceTool.exe) can be used to upgrade Qt to newer versions.

**Install Python**

Get a Python 3.x installer from https://python.org/download/ and install Python into the default location (C:\Python37).

Alternatively you can install Python using Chocolatey:

```
PS$>choco install -y python3
```

Chocolatey installs Python in C:\Python37 by default.

**Install Perl**

Alternatively you can install Perl using Chocolatey:

```
PS$>choco install -y strawberryperl
# ...or...
PS$>choco install -y activeperl
```

**Install Git**

Please note that the following is not required to build Wireshark but can be quite helpful when working with the sources.

Working with the Git source repositories is highly recommended, as described in Obtain the Wireshark sources. It is much easier to update a personal source tree (local repository) with Git rather than downloading a zip file and merging new sources into a personal source tree by hand. It also makes first-time setup easy and enables the Wireshark build process to determine your current source code revision.

There are several ways in which Git can be installed. Most packages are available at the URLs below or via Chocolatey. Note that many of the GUI interfaces depend on the command line version.

If installing the Windows version of git select the Use Git from the Windows Command Prompt (in chocolatey the /GitOnlyOnPath option). Do not select the Use Git and optional Unix tools from the Windows Command Prompt option (in chocolatey the /GitAndUnixToolsOnPath option).
The Official Windows Installer

The official command-line installer is available at https://git-scm.com/download/win.

Git Extensions

Git Extensions is a native Windows graphical Git client for Windows. You can download the installer from https://github.com/gitextensions/gitextensions/releases/latest.

TortoiseGit

TortoiseGit is a native Windows graphical Git similar to TortoiseSVN. You can download the installer from https://tortoisegit.org/download/.

Command Line client via Chocolatey

The command line client can be installed (and updated) using Chocolatey:

```
PS$> choco install -y git
```

Others

A list of other GUI interfaces for Git can be found at https://git-scm.com/downloads/guis

Install CMake

Get the CMake installer from https://cmake.org/download/ and install CMake into the default location. Ensure the directory containing cmake.exe is added to your path.

Alternatively you can install CMake using Chocolatey:

```
PS$>choco install -y cmake
```

Chocolatey ensures cmake.exe is on your path.

Install Asciidoctor, Xsltproc, And DocBook

Asciidoctor can be run directly as a Ruby script or via a Java wrapper (Asciidoc). It is used in conjunction with Xsltproc and DocBook to generate the documentation you’re reading and the User’s Guide.

The easiest way to install them on Windows is via Chocolatey:

```
PS$>choco install -y asciidoctorj xsltproc docbook-bundle
```
Chocolatey ensures that asciidoctorj.exe and xsltproc.exe is on your path and that xsltproc uses the DocBook catalog.

**Install winflexbison**

Get the winFlexBison installer from https://sourceforge.net/projects/winflexbison/ and install into the default location. Ensure the directory containing win_flex.exe and win_bison.exe is on your path.

Alternatively you can install Winflexbison using Chocolatey:

```
PS$>choco install -y winflexbison
```

Chocolatey ensures win_flex.exe and win_bison.exe are on your path.

**Install and Prepare Sources**

*Make sure everything works*

It’s a good idea to make sure Wireshark compiles and runs at least once before you start hacking the Wireshark sources for your own project. This example uses Git Extensions but any other Git client should work as well.

**Download sources** Download Wireshark sources into `C:\Development\wireshark` using either the command line or Git Extensions:

Using the command line:

```
>cd C:\Development
>git clone https://code.wireshark.org/review/wireshark
```

Using Git extensions:

1. Open the Git Extensions application. By default Git Extensions will show a validation checklist at startup. If anything needs to be fixed do so now. You can bring up the checklist at any time via **Tools > Settings**.

2. In the main screen select *Clone repository*. Fill in the following:

   **Repository to clone:** https://code.wireshark.org/review/wireshark

   **Destination:** Your top-level development directory, e.g. `C:\Development`.

   **Subdirectory to create:** Anything you’d like. Usually `wireshark`.

Check your paths
Make sure your repository path doesn’t contain spaces.

3. Click the [Clone] button. Git Extensions should start cloning the Wireshark repository.

Open a Visual Studio Command Prompt

From the Start Menu (or Start Screen), navigate to the “Visual Studio 2019” folder and choose the Command Prompt appropriate for the build you wish to make, e.g. “x64 Native Tools Command Prompt for VS 2019” for a 64-bit version or “x86 Native Tools Command Prompt for VS 2019” for a 32-bit version. Depending on your version of Windows the Command Prompt list might be directly under “Visual Studio 2019” or you might have to dig for it under multiple folders, e.g. Visual Studio 2019 › Visual Studio Tools › Windows Desktop Command Prompts.

Pin the items to the Task Bar
Pin the Command Prompt you use to the Task Bar for easy access.

All subsequent operations take place in this Command Prompt window.

1. Set environment variables to control the build.

Set the following environment variables, using paths and values suitable for your installation:

```bash
> rem Let CMake determine the library download directory name under
> rem WIRESHARK_BASE_DIR or set it explicitly by using WIRESHARK_LIB_DIR.
> rem Set *one* of these.
> set WIRESHARK_BASE_DIR=C:\Development
> rem set WIRESHARK_LIB_DIR=c:\wireshark-win64-libs
> rem Set the Qt installation directory
> set QT5_BASE_DIR=C:\Qt\5.12.5\msvc2017_64
> rem Append a custom string to the package version. Optional.
> set WIRESHARK_VERSION_EXTRA=-YourExtraVersionInfo
```

Setting these variables could be added to a batch file to be run after you open the Visual Studio Tools Command Prompt.

Use Qt’s LTS branch
We recommend using the most recent “long term support” branch of Qt5 to compile Wireshark on Windows. At the time of writing this is Qt 5.12.

2. Create and change to the correct build directory. CMake is best used in an out-of-tree build configuration where the build is done in a separate directory to the source tree, leaving the source tree in a pristine state. 32 and 64 bit builds require a separate build directory. Create (if required) and change to the appropriate build directory.
to create and jump into the build directory.

The build directory can be deleted at any time and the build files regenerated as detailed in Generate the build files.

**Generate the build files**

CMake is used to process the CMakeLists.txt files in the source tree and produce build files appropriate for your system.

You can generate Visual Studio solution files to build either from within Visual Studio, or from the command line with MSBuild. CMake can also generate other build types but they aren't supported.

The initial generation step is only required the first time a build directory is created. Subsequent builds will regenerate the build files as required.

If you've closed the Visual Studio Command Prompt prepare it again.

To generate the build files enter the following at the Visual Studio command prompt:

```text
> cmake -G "Visual Studio 16 2019" -A Win32 ..\wireshark
```

Adjusting the paths as required to Python and the wireshark source tree. To use a different generator modify the `-G` parameter. `cmake -G` lists all the CMake supported generators, but only Visual Studio is supported for Wireshark builds.

To build an x64 version, specify it as the architecture, e.g. `-G "Visual Studio 16 2019" -A x64`:

```text
> cmake -G "Visual Studio 16 2019" -A x64 ..\wireshark
```

The CMake generation process will download the required 3rd party libraries (apart from Qt) as required, then test each library for usability before generating the build files.

At the end of the CMake generation process the following should be displayed:

```text
-- Configuring done
-- Generating done
-- Build files have been written to: C:/Development/wsbuild32
```
If you get any other output, there is an issue in your environment that must be rectified before building. Check the parameters passed to CMake, especially the `-G` option and the path to the Wireshark sources and the environment variables `WIRESHARK_BASE_DIR` and `QT5_BASE_DIR`.

**Build Wireshark**

Now it's time to build Wireshark!

1. If you've closed the Visual Studio Command Prompt prepare it again.
2. Run

   ```
   > msbuild /m /p:Configuration=RelWithDebInfo Wireshark.sln
   ```

   to build Wireshark.

3. Wait for Wireshark to compile. This will take a while, and there will be a lot of text output in the command prompt window
4. Run `C:\Development\wsbuild32\run\RelWithDebInfo\Wireshark.exe` and make sure it starts.
5. Open **Help › About**. If it shows your "private" program version, e.g.: Version 3.1.1-myprotocol123 congratulations! You have compiled your own version of Wireshark!

You may also open the Wireshark solution file (`Wireshark.sln`) in the Visual Studio IDE and build there.

**TIP**
If compilation fails for suspicious reasons after you changed some source files try to clean the build files by running `msbuild /m /p:Configuration=RelWithDebInfo Wireshark.sln /t:Clean` and then building the solution again.

The build files produced by CMake will regenerate themselves if required by changes in the source tree.

**Debug Environment Setup**

You can debug using the Visual Studio Debugger or WinDbg. See the section on using the Debugger Tools.

**Optional: Create User’s and Developer’s Guide**

Detailed information to build these guides can be found in the file `docbook\README.adoc` in the Wireshark sources.
Optional: Create a Wireshark Installer

Note: You should have successfully built Wireshark before doing the following.

If you want to build your own Wireshark-win32-3.1.1-myprotocol123.exe, you'll need NSIS. You can download it from http://nsis.sourceforge.net.

Note that the 32-bit version of NSIS will work for both 32-bit and 64-bit versions of Wireshark. NSIS v3 is required.

Note: For Visual Studio 2015 and earlier, if you do not yet have a copy of vcredist_x86.exe or vcredist_x64.exe in ./wireshark-winXX-libs (where XX is 32 or 64) you will need to download the appropriate file and place it in ./wireshark-winXX-libs before starting this step.

If building an x86 version using a Visual Studio 2015 or earlier “Express” edition or an x64 version with any edi of Visual Studio 2015 or earlier, then you must have the appropriate vcredist file for your compiler in the support libraries directory (vcredist_x86.exe in wireshark-32-libs or vcredist_x64.exe in wireshark-win64-libs).

Note you must use the correct version of vcredist for your compiler, unfortunately they all have the same name (vcredist_x86.exe or vcredist_x64.exe). You can use Windows Explorer and examine the “Properties → Details” tab for a vcredist file to determine which compiler version the file is for use with.

For Visual Studio 2017 and later, all editions include the redistributables, so you do not need to download them.

If you’ve closed the Visual Studio Command Prompt prepare it again.

Run

```bash
> msbuild /m /p:Configuration=RelWithDebInfo nsis_package_prep.vcxproj
> msbuild /m /p:Configuration=RelWithDebInfo nsis_package.vcxproj
```

to build a Wireshark installer. If you sign your executables you should do so between the “nsis_package_prep” and “nsis_package” steps.

Run

```bash
> packaging\nis\wireshark-win64-{wireshark-version}-myprotocol123.exe
```
to test your new installer. It's a good idea to test on a different machine than the developer machine. Note that if you've built an x86 version, the installer name will contain “win32”.
Work with the Wireshark sources

Introduction

This chapter will explain how to work with the Wireshark source code. It will show you how to:

• Get the source
• Compile it on your machine
• Submit changes for inclusion in the official release

This chapter will not explain the source file contents in detail, such as where to find specific functionality. This is done in Source overview.

The Wireshark Git repository

Git is used to keep track of the changes made to the Wireshark source code. The code is stored inside Wireshark project’s Git repository located at a server at the wireshark.org domain.

Changes to the official repository are managed using the Gerrit code review system. Gerrit makes it easy to test and discuss changes before they are pushed to the main repository. For an overview of Gerrit see the Quick Introduction.

Why Git?

Git is a fast, flexible way of managing source code. It allows large scale distributed development and ensures data integrity.

Why Gerrit?

Gerrit makes it easy to contribute. You can sign in with any OpenID provider and push your changes. It's usable from both the web and command line and is integrated with many popular tools.

NOTE

Git is our third revision control system

Wireshark originally used Concurrent Versions System (CVS) and migrated to Subversion in July 2004. The Subversion repository was subsequently migrated to Git in January 2014.

Using Wireshark's Git repository you can:

• Keep your private sources up to date with very little effort
• Get a mail notification when the official source code changes
• Get the source files from any previous release (or any other point in time)
• Have a quick look at the sources using a web interface
• See which person changed a specific piece of code
• and much more

The web interface to the Git repository

If you need a quick look at the Wireshark source code you can browse the most recent file versions in the master branch using Gitweb:

https://code.wireshark.org/review/gitweb?p=wireshark.git;a=tree

You can also view commit logs, branches, tags, and past revisions:

https://code.wireshark.org/review/gitweb?p=wireshark.git

Git Naming Conventions

Like most revision control systems, Git uses branching to manage different copies of the source code and allow parallel development. Wireshark uses the following branch naming conventions:

• master: Main feature development and odd-numbered “development” releases.
• master-x.y: Stable release maintenance. For example, master-3.0 is used to manage the 3.0.x official releases.

Tags for major releases and release candidates consist of a “v” followed by a version number such as “v3.0.1” or “v3.0.3rc0”. Major releases additionally have a tag prefixed with “wireshark-” followed by a version number, such as “wireshark-3.0.0”.

Obtain the Wireshark sources

There are several ways to obtain the sources from Wireshark’s Git repository.

TIP

Check out from the master branch using Git.

Using Git is much easier than synchronizing your source tree by hand using any of the snapshot methods mentioned below. Git merges changes into your personal source tree in a very comfortable and quick way. So you can update your source tree several times a day without much effort.

NOTE

Keep your sources up to date

The following ways to retrieve the Wireshark sources are sorted in decreasing source timeliness. If you plan to commit changes you’ve made to the sources, it’s a good idea to keep your private source tree as current as possible.

The age mentioned in the following sections indicates the age of the most recent change in that set of the sources.
**Git over SSH or HTTPS**

Recommended for development purposes.

Age: a few minutes.

You can use a Git client to download the source code from Wireshark’s code review system. Anyone can clone from the anonymous git URL:

- https://code.wireshark.org/review/wireshark

If you create a Gerrit account you can clone from an authenticated URL:

- ssh://your.username@code.wireshark.org:29418/wireshark
- https://your.username@code.wireshark.org/review/wireshark

SSH lets you use Gerrit on the command line. HTTP lets you access the repository in environments that block the Gerrit SSH port (29418). At the time of this writing (early 2014) we recommend that you use the SSH interface. However, this may change as more tools take advantage of Gerrit’s HTTP REST API.

The following example shows how to get up and running on the command line. See Git client for information on installing and configuring graphical Git and Gerrit clients.

1. Sign in to https://code.wireshark.org/review using OpenID (click Register or Sign In in the upper right corner of the web page). Follow the login instructions.

2. In the upper right corner of the web page, click on your account name and select Settings.

3. Under Profile set a username. This will be the username that you use for SSH access. For the steps below we’ll assume that your username is **henry.perry**.

4. Select SSH Public Keys and add one or more keys. You will typically upload a key for each computer that you use.

5. Install git-review. This is an installable package in many Linux distributions. You can also install it as a Python package. (This step isn’t strictly necessary but it makes working with Gerrit much easier.) To install it from Chocolatey run
6. Now on to the command line. First, make sure *git* works:

```bash
$ git --version
```

7. If this is your first time using Git, make sure your username and email address are configured. This is particularly important if you plan on uploading changes.

```bash
$ git config --global user.name "Henry Perry"
$ git config --global user.email henry.perry@example.com
```

8. Next, clone the Wireshark repository:

```bash
$ git clone ssh://henry.perry@code.wireshark.org:29418/wireshark
```

The clone only has to be done once. This will copy all the sources (including directories) from the server to your machine and check out the latest version. This may take some time depending on the speed of your internet connection.

9. Then set up the *git* pre-commit hook and the push address:

```bash
$ cd wireshark
$ cp tools/pre-commit .git/hooks/
$ git config --add remote.origin.push HEAD:refs/for/master
```

This will run a few basic checks on commit to make sure that the code does not contain trivial errors. It will also warn if it is out of sync with its master copy in the tools/ directory. The change in the push address is necessary: We have an asymmetric process for pulling and pushing because of gerrit.

10. Initialize *git-review*. 
$ git review -s

This prepares your local repository for use with Gerrit, including installing the `commit-msg` hook script.

**Git web interface**

Recommended for informational purposes only, as only individual files can be downloaded.

Age: a few minutes (same as anonymous Git access).

The entire source tree of the Git repository is available via a web interface at [https://code.wireshark.org/review/gitweb?p=wireshark.git](https://code.wireshark.org/review/gitweb?p=wireshark.git). You can view each revision of a particular file, as well as diffs between different revisions. You can also download individual files but not entire directories.

**Buildbot Snapshots**

Recommended for development purposes, if direct Git access isn’t possible (e.g. because of a restrictive firewall).

Age: some number of minutes (a bit older than the Git access).

The Buildbot server will automatically start to generate a snapshot of Wireshark’s source tree after a source code change is committed. These snapshots can be found at [https://www.wireshark.org/download/automated/src/](https://www.wireshark.org/download/automated/src/).

If Git access isn't possible, e.g. if the connection to the server isn't possible because of a corporate firewall, the sources can be obtained by downloading the Buildbot snapshots. However, if you are going to maintain your sources in parallel to the "official" sources for some time, it's recommended to use the anonymous (or authenticated) Git access if possible (believe it, it will save you a lot of time).

**Released sources**

Recommended for building pristine packages.

Age: from days to weeks.

The official source releases can be found at [https://www.wireshark.org/download.html](https://www.wireshark.org/download.html). You should use these sources if you want to build Wireshark on your platform for with minimal or no changes, such Linux distribution packages.

The differences between the released sources and the sources in the Git repository will keep on growing until the next release is made. (At the release time, the released and latest Git repository
versions are identical again :-).

## Update the Wireshark sources

After you've obtained the Wireshark sources for the first time, you might want to keep them in sync with the sources at the upstream Git repository.

### TIP

**Take a look at the Buildbot first**

As development evolves, the Wireshark sources are compilable most of the time — but not always. You should take a look at [https://buildbot.wireshark.org/wireshark-master/waterfall](https://buildbot.wireshark.org/wireshark-master/waterfall) before fetching or pulling to make sure the builds are in good shape.

### Update Using Git

After you clone Wireshark's Git repository you can update by running

```bash
$ git status
$ git pull
```

Depending on your preferences and work habits you might want to run `git pull --rebase` or `git checkout -b my-topic-branch origin/master` instead.

Fetching should only take a few seconds, even on a slow internet connection. It will update your local repository history with changes from the official repository. If you and someone else have changed the same file since the last update, Git will try to merge the changes into your private file (this works remarkably well).

### Update Using Source Archives

There are several ways to download the Wireshark source code (as described in [Obtain the Wireshark sources](#)), but bringing the changes from the official sources into your personal source tree is identical.

First of all, you will download the new `.tar.xz` file of the official sources the way you did it the first time.

If you haven't changed anything in the sources, you could simply throw away your old sources and reinstall everything just like the first time. But be sure, that you really haven't changed anything. It might be a good idea to simply rename the "old" dir to have it around, just in case you remember later that you really did change something before.

If you have changed your source tree, you have to merge the official changes since the last update into your source tree. You will install the content of the `.tar.xz` file into a new directory and use a good merge tool (e.g. [http://winmerge.sourceforge.net/](http://winmerge.sourceforge.net/) for Windows) to bring your personal source
tree in sync with the official sources again.

This method can be problematic and can be much more difficult and error-prone than using Git.

# Build Wireshark

The sources contain several documentation files. It’s a good idea to read these files first. After obtaining the sources, tools and libraries, the first place to look at is `doc/README.developer`. Inside you will find the latest information for Wireshark development for all supported platforms.

**TIP**

*Build Wireshark before changing anything*

It is a very good idea to first test your complete build environment (including running and debugging Wireshark) before making any changes to the source code (unless otherwise noted).

Building Wireshark for the first time depends on your platform.

## Building on Unix

The recommended (and fastest) way to build Wireshark is with CMake and Ninja:

```bash
# Starting from your Wireshark source directory, create a build directory
# alongside it.
$ cd ..
$ mkdir wireshark-ninja
$ cd wireshark-ninja
# Assumes your source directory is named "wireshark".
$ cmake -G Ninja ..\wireshark
$ ninja (or cmake --build .)
```

If you need to build with a non-standard configuration, you can run

```bash
$ cmake -LH ..\wireshark
```

to see what options you have.

## Windows native

Follow the build procedure in [Build Wireshark](#) to build Wireshark.

After the build process has successfully finished, you should find a `Wireshark.exe` and some other files in the `run\RelWithDebInfo` directory.
Run generated Wireshark

Beware of multiple Wiresharks

An already installed Wireshark may interfere with your newly generated version in various ways. If you have any problems getting your Wireshark running the first time, it might be a good idea to remove the previously installed version first.

Unix-like platforms

After a successful build you can run Wireshark right from the build directory. Still the program would need to know that it’s being run from the build directory and not from its install location. This has an impact on the directories where the program can find the other parts and relevant data files.

In order to run the Wireshark from the build directory set the environment variable WIRESHARK_RUN_FROM_BUILD_DIRECTORY and run Wireshark. If your platform is properly setup, your build directory and current working directory are not in your PATH, so the command line to launch Wireshark would be:

```
$ WIRESHARK_RUN_FROM_BUILD_DIRECTORY=1 ./run/wireshark
```

There’s no need to run Wireshark as root user, you just won’t be able to capture. When you opt to run Wireshark this way, your terminal output can be informative when things don’t work as expected.

Windows native

During the build all relevant program files are collected in a subdirectory run\RelWithDebInfo. You can run the program from there by launching the Wireshark.exe executable.

Debug Your Generated Wireshark

Unix-Like Platforms

You can debug using command-line debuggers such as gdb, dbx, or lldb. If you prefer a graphic debugger, you can use an IDE or debugging frontend such as Qt Creator, CLion, or Eclipse.

Additional traps can be set on GLib by setting the G_DEBUG environment variable:

```
$ G_DEBUG=fatal_criticals gdb wireshark
```

Windows native

You can debug using the Visual Studio Debugger or WinDbg. See the section on using the Debugger Tools.

Make changes to the Wireshark sources

As the Wireshark developers are working on many different platforms, a lot of editors are used to develop Wireshark (emacs, vi, Microsoft Visual Studio and many, many others). There’s no "standard" or "default" development environment.

There are several reasons why you might want to change the Wireshark sources:

• Add support for a new protocol (a new dissector)
• Change or extend an existing dissector
• Fix a bug
• Implement a glorious new feature

The internal structure of the Wireshark sources will be described in Wireshark Development.

<table>
<thead>
<tr>
<th>TIP</th>
</tr>
</thead>
</table>
| *Ask the wireshark-dev mailing list before you start a new development task.*

If you have an idea what you want to add or change it’s a good idea to contact the developer mailing list (see Mailing Lists) and explain your idea. Someone else might already be working on the same topic, so a duplicated effort can be reduced. Someone might also give you tips that should be thought about (like side effects that are sometimes very hard to see).

Contribute your changes

If you have finished changing the Wireshark sources to suit your needs, you might want to contribute your changes back to the Wireshark community. You gain the following benefits by contributing your improvements:

• *It’s the right thing to do.* Other people who find your contributions useful will appreciate them, and you will know that you have helped people in the same way that the developers of Wireshark have helped you.

• *You get free enhancements.* By making your code public, other developers have a chance to make improvements, as there’s always room for improvements. In addition someone may implement advanced features on top of your code, which can be useful for yourself too.

• *You save time and effort.* The maintainers and developers of Wireshark will maintain your code as well, updating it when API changes or other changes are made, and generally keeping it in tune with what is happening with Wireshark. So if Wireshark is updated (which is done often), you can get a new Wireshark version from the website and your changes will already be
There's no direct way to push changes to the Git repository. Only a few people are authorised to actually make changes to the source code (check-in changed files). If you want to submit your changes, you should upload them to the code review system at https://code.wireshark.org/review. This requires you to set up git as described at Git over SSH or HTTPS.

Some Tips For A Good Patch

Some tips that will make the merging of your changes into Git much more likely (and you want exactly that, don’t you?):

• Use the latest Git sources. It’s a good idea to work with the same sources that are used by the other developers. This usually makes it much easier to apply your patch. For information about the different ways to get the sources, see Obtain the Wireshark sources.

• Update your sources just before making a patch. For the same reasons as the previous point.

• Inspect your patch carefully. Run git diff and make sure you aren’t adding, removing, or omitting anything you shouldn’t.

• Find a good descriptive topic name for your patch. Short, specific names are preferred. snowcone-machine-protocol is good, your name or your company name isn’t.

• Don’t put unrelated things into one large patch. A few smaller patches are usually easier to apply (but also don’t put every changed line into a separate patch).

In general, making it easier to understand and apply your patch by one of the maintainers will make it much more likely (and faster) that it will actually be applied.

Please remember

Wireshark is a volunteer effort. You aren’t paying to have your code reviewed and integrated.

Writing a Good Commit Message

When running git commit, you will be prompted to describe the change. Here are some guidelines on how to make that message actually useful to other people (and to scripts that may try to parse it):

• Provide a very brief description (under 60 characters) of the change in the first line. If the change is specific to a single protocol, start this line with the abbreviated name of the protocol and a colon. If the change is not complete yet prefix the line with [WIP] to inform this change not to be submitted yet. This can later be removed.

• Insert a single blank line after the first line.

• Provide a detailed description of the change in the following lines, breaking paragraphs where needed. Limit each line to 80 characters. You can also add metadata at the bottom of the commit
message which will be used by Gerrit for searching and triggering Bugzilla integration. Each line of the footer is of the form Label: value. There can be no extra line-breaks between footer lines.

Wireshark currently supports the following metadata tags:

Table 2. Commit message tags

<table>
<thead>
<tr>
<th>Tag</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change-id</td>
<td>A unique hash describing the change, which is generated automatically by the git commit-msg hook which you installed during setup. This should not be changed, even when rebasing or amending a commit following code review. If you pass --no-verify to git commit you will have to add this line yourself.</td>
</tr>
<tr>
<td>Bug</td>
<td>Make Gerrit automatically add a comment and close the given bug number when the commit is merged. For use when the change does fully fix the issue.</td>
</tr>
<tr>
<td>Ping-Bug</td>
<td>Make Gerrit just add a comment to the referenced bug. For use when the change is related but does not fully fix the issue.</td>
</tr>
</tbody>
</table>

**NOTE** The Bug and Ping-Bug tags are particularly useful if a capture file has been provided via a Bugzilla entry in parallel with the change. All non-trivial fixes to dissectors should try to do this.

Putting all that together, we get the following example:

MIPv6: fix dissection of Service Selection Identifier

APN field is not encoded as a dotted string so the first character is not a length

Bug: 10323
Change-Id: Ia62137c785d505e9d0f1536a333b421a85480741

**Code Requirements**

The core maintainers have done a lot of work fixing bugs and making code compile on the various platforms Wireshark supports.

To ensure Wireshark’s source code quality, and to reduce the workload of the core maintainers, there are some things you should think about before submitting a patch.
Pay attention to the coding guidelines

Ignoring the code requirements will make it very likely that your patch will be rejected.

- **Follow the Wireshark source code style guide.** Just because something compiles on your platform, that doesn't mean it'll compile on all of the other platforms for which Wireshark is built. Wireshark runs on many platforms, and can be compiled with a number of different compilers. See [Coding Style](#) for details.

- **Submit dissectors as built-in whenever possible.** Developing a new dissector as a plugin is a good idea because compiling and testing is quicker, but it's best to convert dissectors to the built-in style before submitting for check in. This reduces the number of files that must be installed with Wireshark and ensures your dissector will be available on all platforms.

  This is no hard-and-fast rule though. Many dissectors are straightforward so they can easily be put into "the big pile", while some are ASN.1 based which takes a different approach, and some multiple source file dissectors are more suitable to be placed separately as plugins.

- **Ensure Wireshark Git Pre-Commit Hook is in the repository.** In your local repository directory, there will be a .git/hooks/ directory, with sample git hooks for running automatic actions before and after git commands. You can also optionally install other hooks that you find useful.

  In particular, the pre-commit hook will run every time you commit a change and can be used to automatically check for various errors in your code. The sample git pre-commit hook simply detects whitespace errors such as mixed tabs and spaces; to install it just remove the .sample suffix from the existing pre-commit.sample file.

  Wireshark provides a custom pre-commit hook which does additional Wireshark-specific API and formatting checks, but it might return false positives. If you want to install it, copy the pre-commit file from the tools directory (cp ./tools/pre-commit .git/hooks/) and make sure it is executable or it will not be run.

  If the pre-commit hook is preventing you from committing what you believe is a valid change, you can run git commit --no-verify to skip running the hooks. Warning: using --no-verify avoids the commit-msg hook, and thus will not automatically add the required Change-ID to your commit. In case you are not updating an existing patch you may generate a Change-ID by running git review -i (or git commit --amend if don’t use git review).

  Additionally, if your system supports symbolic links, as all UNIX-like platforms do, you can use them instead of copying files. Running ln -s ./tools/pre-commit .git/hooks creates a symbolic link that will make the hook to be up-to-date with the current master. The same can be done for commit-msg script.

- **Fuzz test your changes!** Fuzz testing is a very effective way to automatically find a lot of dissector related bugs. You'll take a capture file containing packets affecting your dissector and the fuzz test will randomly change bytes in this file, so that unusual code paths in your dissector
are checked. There are tools available to automatically do this on any number of input files, see: https://wiki.wireshark.org/FuzzTesting for details.

Uploading your changes

When you're satisfied with your changes (and obtained any necessary approval from your organization) you can upload them for review at https://code.wireshark.org/review. This requires a Gerrit Code Review account as described at The Wireshark Git repository.

Changes should be pushed to a magical "refs/for" branch in Gerrit. For example, to upload your new Snowcone Machine Protocol dissector you could push to refs/for/master with the topic "snowcone-machine":

```
$ git push ssh://my.username@code.wireshark.org:29418/wireshark
HEAD:refs/for/master/snowcone-machine
```

The username my.username is the one which was given during registration with the review system.

If you have git-review installed you can upload the change with a lot less typing:

```
# Note: The "-f" flag deletes your current branch.
$ git review -f
```

You can push using any Git client. Many clients have support for Gerrit, either built in or via an additional module.

The Change-Id is very relevant in the review process, since it's the key used to identify one change. See the Gerrit manual for more details.

You might get one of the following responses to your patch request:

- Your patch is checked into the repository. Congratulations!
- You are asked to provide additional information, capture files, or other material. If you haven't fuzzed your code, you may be asked to do so.
- Your patch is rejected. You should get a response with the reason for rejection. Common reasons include not following the style guide, buggy or insecure code, and code that won't compile on other platforms. In each case you'll have to fix each problem and upload another patch.
- You don't get any response to your patch. Possible reason: All the core developers are busy (e.g., with their day jobs or family or other commitments) and haven't had time to look at your patch. Don't worry, if your patch is in the review system it won't get lost.

If you're concerned, feel free to add a comment to the patch or send an email to the developer's list asking for status. But please be patient: most if not all of us do this in our spare time.
Backporting a change

When a bug is fixed in the master branch it might be desirable or necessary to backport the fix to a stable branch. You can do this in Git by cherry-picking the change from one branch to another. Suppose you want to backport change 1ab2c3d4 from the master branch to master-1.10. Using "pure Git" commands you would do the following:

```bash
# Create a new topic branch for the backport.
$ git checkout -b backport-1ab2c3d4 origin/master-1.10

# Cherry-pick the change. Include a "cherry picked from..." line.
$ git cherry-pick -x 1ab2c3d4

# If there are conflicts, fix them.
# Compile and test the change.
$ make
$ ...

# OPTIONAL: Add entries to docbook/release-notes.adoc.
$ $EDITOR docbook/release-notes.adoc

# If you made any changes, update your commit:
$ git commit --amend -a

# Upload the change to Gerrit
$ git push ssh://my.username@code.wireshark.org:29418/wireshark HEAD:refs/for/master-1.10/backport-1ab2c3d4
```

If you want to cherry-pick a Gerrit change ID (e.g. I5e6f7890) you can use `git review -X I5e6f7890` instead of `git cherry-pick` and `git review` instead of `git push` as described in the previous chapter.

Apply a patch from someone else

Sometimes you need to apply a patch to your private source tree. Maybe because you want to try a patch from someone on the developer mailing list, or you want to check your own patch before submitting.

**WARNING**

*Beware line endings*

If you have problems applying a patch, make sure the line endings (CR/LF) of the patch and your source files match.
Using patch

Given the file `new.diff` containing a unified diff, the right way to call the patch tool depends on what the pathnames in `new.diff` look like. If they're relative to the top-level source directory (for example, if a patch to `prefs.c` just has `prefs.c` as the file name) you'd run it as:

```bash
$ patch -p0 < new.diff
```

If they're relative to a higher-level directory, you'd replace 0 with the number of higher-level directories in the path, e.g. if the names are `wireshark.orig/prefs.c` and `wireshark.mine/prefs.c`, you'd run it with:

```bash
$ patch -p1 < new.diff
```

If they're relative to a subdirectory of the top-level directory, you'd run `patch` in that directory and run it with `-p0`.

If you run it without `-pat all, the patch tool flattens path names, so that if you have a patch file with patches to `CMakeLists.txt` and `wiretap/CMakeLists.txt`, it'll try to apply the first patch to the top-level `CMakeLists.txt` and then apply the `wiretap/CMakeLists.txt` patch to the top-level `CMakeLists.txt` as well.

At which position in the filesystem should the patch tool be called?

If the pathnames are relative to the top-level source directory, or to a directory above that directory, you’d run it in the top-level source directory.

If they’re relative to a subdirectory — for example, if somebody did a patch to `packet-ip.c` and ran `diff` or `git diff` in the `epan/dissectors` directory — you’d run it in that subdirectory. It is preferred that people not submit patches like that, especially if they’re only patching files that exist in multiple directories such as `CMakeLists.txt`.

Binary Packaging

Delivering binary packages makes it much easier for the end-users to install Wireshark on their target system. This section will explain how the binary packages are made.

Packaging Guidelines

The following guidelines should be followed by anyone creating and distributing third-party Wireshark packages or redistributing official Wireshark packages.

Spelling And Capitalization
Wireshark is spelled with a capital “W”, and with everything else lower case. “WireShark” in particular is incorrect.

Main URL

The official Wireshark project URL is https://www.wireshark.org/.

Download URLs

Official packages are distributed on the main web server (www.wireshark.org) and a number of download mirrors. The canonical locations for packages are in the all_versions subdirectories on each server.

For example, if your packaging system links to or downloads the source tarball and you want to download from 1.na.dl.wireshark.org, use

https://1.na.dl.wireshark.org/download/src/all-versions/wireshark-3.1.1.tar.xz

instead of

https://1.na.dl.wireshark.org/download/src/wireshark-3.1.1.tar.xz

Artwork

Logo and icon artwork can be found in the image directory in the distribution. This is available online at

https://code.wireshark.org/review/gitweb?p=wireshark.git;a=tree;f=image;hb=HEAD

Licensing

Wireshark is released under the GNU General Public License version 2 or later. Make sure you and your package comply with this license.

Trademarks

Wireshark and the “fin” logo are registered trademarks of the Wireshark Foundation. Make sure you and your package comply with trademark law.

Privileges

All function calls that require elevated privileges are in dumpcap.

WIRESHARK CONTAINS OVER THREE MILLION LINES OF SOURCE CODE. DO NOT RUN THEM AS ROOT.

Warnings are displayed when Wireshark and TShark are run as root.

There are two configure-time options on non-Windows systems that affect the privileges a normal
user needs to capture traffic and list interfaces:

-DDUMPCAP_INSTALL_OPTION=capabilities
  Install dumpcap with cap_net_admin and cap_net_raw capabilities. Linux only.

-DDUMPCAP_INSTALL_OPTION=suid
  Install dumpcap setuid root.

These are necessary for non-root users to be able to capture on most systems, e.g. on Linux or FreeBSD if the user doesn't have permissions to access /dev/bpf*. Setcap installation is preferred over setuid on Linux. If -DDUMPCAP_INSTALL_OPTION=capabilities is used it will override any setuid settings.

The -DENABLE_CAP option is only useful when dumpcap is installed setuid. If it is enabled dumpcap will try to drop any setuid privileges it may have while retaining the CAP_NET_ADMIN and CAP_NET_RAW capabilities. It is enabled by default, if the Linux capabilities library (on which it depends) is found.

Note that enabling setcap or setuid installation allows packet capture for ALL users on your system. If this is not desired, you can restrict dumpcap execution to a specific group or user. The following two examples show how to restrict access using setcap and setuid respectively:

```
# groupadd -g packetcapture
# chmod 750 /usr/bin/dumpcap
# chgrp packetcapture /usr/bin/dumpcap
# setcap cap_net_raw,cap_net_admin+ep /usr/bin/dumpcap

# groupadd -g packetcapture
# chgrp packetcapture /usr/bin/dumpcap
# chmod 4750 /usr/bin/dumpcap
```

**Customization**

Custom version information can be added by running tools/make-version.pl. If your package contains significant changes we recommend that you use this to differentiate it from official Wireshark releases.

```
$ tools/make-version.pl --set-release --untagged-version-extra=-{vcsinfo}-FooCorp
--tagged-version-extra=-FooCorp
```

See tools/make-version.pl for details.

The Git version corresponding to each release is in version.h. It's defined as a string. If you need a numeric definition, let us know.

If you have a question not addressed here, please contact wireshark-dev[AT]wireshark.org.
**Debian: .deb Packages**

The Debian Package is built using dpkg-buildpackage, based on information found in the source tree under *debian*. See [https://www.debian.org/doc/manuals/maint-guide/build.en.html](https://www.debian.org/doc/manuals/maint-guide/build.en.html) for a more in-depth discussion of the build process.

In the wireshark directory, type:

```
$ dpkg-buildpackage -b -us -uc -jauto
```

to build the Debian Package.

**Red Hat: .rpm Packages**

You can build an RPM package using the `rpm-package` target. The package version is derived from the current git HEAD, so you must build from a git checkout.

The package is built using `rpmbuild`, which comes as standard on many flavours of Linux, including Red Hat, Fedora, and openSUSE. The process creates a clean build environment in `${CMAKE_BINARY_DIR}/packaging/rpm/BUILD` each time the RPM is built. The settings that control the build are in `${CMAKE_SOURCE_DIR}/packaging/rpm/wireshark.spec.in`. The generated SPEC file contains CMake flags and other settings for the RPM build environment. Many of these come from the parent CMake environment. Notable ones are:

- `_prefix` is set to `CMAKE_INSTALL_PREFIX`. By default this is `/usr/local`. Pass `-DCMAKE_INSTALL_PREFIX=/usr` to create a package that installs into `/usr`.
- Whether or not to create the “wireshark-qt” package (`-DBUILD_wireshark`).
- Lua, c-ares, nghttp2, and other library support (`-DENABLE_…`).
- Building with Ninja (`-G Ninja`).

In your build directory, type:

```
$ ninja rpm-package
# ...or, if you're using GNU make...
$ make rpm-package
```

to build the binary and source RPMs. When it is finished there will be a message stating where the built RPM can be found.
This might take a while

This creates a tarball, extracts it, compiles Wireshark, and constructs a package. This can take quite a long time. You can speed up the process by using Ninja. If you're using GNU make you can add the following to your 

\texttt{~/.rpmmacros} file to enable parallel builds:

\texttt{\%_smp_mflags -j \(\%(\text{grep -c processor /proc/cpuinfo)}\)}

Building the RPM package requires quite a few packages and libraries including GLib, gcc, bison, flex, Asciidoctor, and Qt development tools such as uic and moc. The required Qt packages can usually be obtained by installing the qt5-devel package. For a complete list of build requirements, look for the “BuildRequires” lines in packaging/rpm/wireshark.spec.in.

**macOS: .dmg Packages**

The macOS Package is built using macOS packaging tools, based on information found in the source tree under packaging/macosx. It requires Asciidoctor and dmgbuild. In your build directory, type:

\texttt{
$ make dmg_package
}

to build the macOS Package.

**Windows: NSIS .exe Installer**

The Nullsoft Install System is a free installer generator for Windows systems. Instructions on installing it can be found in Windows: NSIS (Optional). NSIS is script based. You can find the main Wireshark installer generation script at packaging/nsis/wireshark.nsi.

When building with CMake you must first build the \texttt{nsis\_package\_prep} target, followed by the \texttt{nsis\_package} target, e.g.

\texttt{
> msbuild /m /p:Configuration=RelWithDebInfo nsis\_package\_prep.vcxproj
> msbuild /m /p:Configuration=RelWithDebInfo nsis\_package.vcxproj
}

Splitting the packaging projects in this way allows for code signing.

This might take a while

Please be patient while the package is compressed. It might take some time, even on fast machines.

If everything went well, you will now find something like: wireshark-setup-3.1.1.exe in the packaging/nsis directory in your build directory.
Windows: PortableApps .paf.exe Package

PortableApps.com is an environment that lets users run popular applications from portable media such as flash drives and cloud drive services.

Install the PortableApps.com Platform. Install for “all users”, which will place it in C:\PortableApps. Add the following apps:

- NSIS Portable (Unicode)
- PortableApps.com Installer
- PortableApps.com Launcher
- PortableApps.com AppCompactor

When building with CMake you must first build the nsis_package_prep target (which takes care of general packaging dependencies), followed by the portableapps_package target, e.g.

```bash
> msbuild /m /p:Configuration=RelWithDebInfo nsis_package_prep.vcxproj
> msbuild /m /p:Configuration=RelWithDebInfo portableapps_package.vcxproj
```

**TIP**

This might take a while

Please be patient while the package is compressed. It might take some time, even on fast machines.

If everything went well, you will now find something like: WiresharkPortable3.1.1.paf.exe in the packaging/portableapps directory.
Tool Reference

Introduction

This chapter will provide you with information about the various tools needed for Wireshark development. None of the tools mentioned in this chapter are needed to run Wireshark. They are only needed to build it.

Most of these tools have their roots on UNIX or UNIX-like platforms such as Linux, but Windows ports are also available. Therefore the tools are available in different "flavours":

- UNIX and UNIX-like platforms: The tools should be commonly available on the supported UNIX and UNIX-like platforms. Cygwin is unsupported.

- Windows native: Some tools are available as native Windows tools, no special emulation is required. Many of these tools can be installed (and updated) using Chocolatey, a Windows package manager similar to the Linux package managers apt-get or yum.

WARNING

Follow the directions

Unless you know exactly what you are doing, you should strictly follow the recommendations given in Quick Setup.

The following sections give a very brief description of what a particular tool is doing, how it is used in the Wireshark project and how it can be installed and tested.

Documentation for these tools is outside the scope of this document. If you need further information on using a specific tool you should find lots of useful information on the web, as these tools are commonly used. You can also get help for the UNIX based tools with `toolname --help` or the man page via `man toolname`.

You will find explanations of the tool usage for some of the specific development tasks in Work with the Wireshark sources.

Chocolatey

Chocolatey is a Windows package manager that can be used to install (and update) many of the packages required for Wireshark development. Chocolatey can be obtained from the website or from a Command Prompt:

```
C:\> @powershell -NoProfile -ExecutionPolicy unrestricted -Command "iex ((new-object net.webclient).DownloadString(_https://chocolatey.org/install.ps1_))" &
Set PATH=%PATH%;%ALLUSERSPROFILE%\chocolatey\bin
```

or a Powershell prompt:
Chocolatey sometimes installs packages in unexpected locations. Python is a notable example. While it's typically installed in a top-level directory, e.g. `C:\Python37` or in `%PROGRAMFILES%`, e.g. `C:\Program Files\Python37`, Chocolatey tends to install it under `C:\ProgramData\chocolatey` or `C:\Tools`. If you want to avoid this behavior you'll probably want to install Python using the packages from python.org.

**CMake**

Wireshark's build environment can be configured using CMake on various UNIX-like platforms, including Linux, macOS, and *BSD, and on Windows. CMake is designed to support out-of-tree builds - so much so that in-tree builds do not work properly in all cases. Along with being cross-platform, CMake supports many build tools and environments including traditional make, Ninja, and MSBuild. Our Buildbot runs CMake steps on Ubuntu, Win32, Win64, and macOS. In particular, the macOS and Windows packages are built using CMake.

Building with CMake typically includes creating a build directory and specifying a **generator**, aka a build tool. For example, to build Wireshark using Ninja in the directory `wireshark-ninja` you might run the following commands:

```bash
# Starting from your Wireshark source directory, create a build directory
# alongside it.
$ cd ..
$ mkdir wireshark-ninja
$ cd wireshark-ninja
# Assumes your source directory is named "wireshark".
$ cmake -G Ninja ../wireshark
$ ninja (or cmake --build .)
```

Using CMake on Windows is described further in [Generate the build files](#).

Along with specifying a generator with the `-G` flag you can set variables using the `-D` flag. Useful variables and generators include the following:

**-DBUILD_wireshark=OFF**

Don't build the Wireshark GUI application. Each command line utility has its own BUILD_xxx flag as well. For example, you can use `-DBUILD_mmdbresolve=OFF` to disable mmdbresolve.

**-DENABLE_CAP=OFF**

Disable the POSIX capabilities check
-DCMAKE_BUILD_TYPE=Debug
   Enable debugging symbols

-DCARES_INCLUDE_DIR=/your/custom/cares/include,
-DCARES_LIBRARY=/your/custom/cares/lib/libcares.so
   Let you set the path to a locally-compiled version of c-ares. Most optional libraries have
   xxx_INCLUDE_DIR and xxx_LIB flags that let you control their discovery.

-DENABLE_APPLICATION_BUNDLE=OFF
   Disable building an application bundle (Wireshark.app) on macOS

You can list all build variables (with help) by running cmake -LH [options]
../<Name_of_WS_source_dir>. This lists the cache of build variables after the cmake run. To only view
the current cache, add option -N.

After running cmake, you can always run make help to see a list of all possible make targets.

Note that CMake honors user umask for creating directories as of now. You should set the umask
explicitly before running the install target.

About CMake in general and why KDE4 uses it: https://lwn.net/Articles/188693/

Useful variables: https://gitlab.kitware.com/cmake/community/wikis/doc/cmake/Useful-Variables

Frequently Asked Questions: https://gitlab.kitware.com/cmake/community/wikis/FAQ

GNU Compiler Toolchain (UNIX And UNIX-like Platforms)

gcc (GNU Compiler Collection)

The GCC C compiler is available for most UNIX and UNIX-like operating systems.

If GCC isn't already installed or available as a package for your platform, you can get it at:

After correct installation, typing at the bash command line prompt:

$ gcc --version
should result in something like

```shell
$ gcc --version
```

Your version string may vary, of course.

**gdb (GNU Project Debugger)**

GDB is the debugger for the GCC compiler. It is available for many (if not all) UNIX-like platforms.

If you don't like debugging using the command line, many GUI frontends for it available, including Qt Creator, CLion, and Eclipse.

If gdb isn't already installed or available as a package for your platform, you can get it at: https://www.gnu.org/software/gdb/gdb.html.

After correct installation:

```shell
$ gdb --version
```

should result in something like:

```shell
GNU gdb (GDB) 8.3
Copyright (C) 2019 Free Software Foundation, Inc.
License GPLv3+: GNU GPL version 3 or later <http://gnu.org/licenses/gpl.html>
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law.
```

Your version string may vary, of course.

**make (GNU Make)**

**NOTE**

*GNU make isn't supported either for Windows*

GNU Make is available for most of the UNIX-like platforms.

If GNU Make isn't already installed or available as a package for your platform, you can get it at: https://www.gnu.org/software/make/.

After correct installation:
$ make --version

should result in something like:

```
GNU Make 4.0
Built for x86_64-pc-linux-gnu
Copyright (C) 1988-2013 Free Software Foundation, Inc.
Licence GPLv3+: GNU GPL version 3 or later <http://gnu.org/licenses/gpl.html>
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law.
```

Your version string may vary, of course.

**Ninja**

Ninja is an alternative to make, and is available for many of the UNIX-like platforms. It runs builds faster than make does.

It is designed to have its build files generated by tools such as CMake; to generate build files for Ninja, run CMake with the `-G Ninja` flag.

If Ninja isn’t already installed, see the list of suggestions for Ninja packages at: https://github.com/ninja-build/ninja/wiki/Pre-built-Ninja-packages.

If Ninja isn’t already installed and isn’t available as a package for your platform, you can get it from: https://ninja-build.org. You can download the source code or binaries for Linux, macOS, and Windows (we have not tested Ninja on Windows).

**Microsoft compiler toolchain (Windows native)**

To compile Wireshark on Windows using the Microsoft C/C++ compiler, you’ll need:

1. C compiler (`cl.exe`)
2. Assembler (`ml.exe` for 32-bit targets and `ml64.exe` for 64-bit targets)
3. Linker (`link.exe`)
4. Resource Compiler (`rc.exe`)
5. C runtime headers and libraries (e.g. `stdio.h`, `vcruntime140.lib`)
6. Windows platform headers and libraries (e.g. `windows.h`, `WS2_32.lib`)
7. HTML help headers and libraries (`htmlhelp.h`, `htmlhelp.lib`)
Official Toolchain Packages And Alternatives

Official releases are or were built with the following Visual C++ versions:

- Wireshark 2.4.x: Microsoft Visual C++ 2015.
- Wireshark 2.2.x: Microsoft Visual C++ 2013.
- Wireshark 1.10.x: Microsoft Visual C++ 2010 SP1.
- Wireshark 1.8.x: Microsoft Visual C++ 2010 SP1.
- Wireshark 1.6.x: Microsoft Visual C++ 2008 SP1.
- Wireshark 1.4.x: Microsoft Visual C++ 2008 SP1.
- Wireshark 1.2.x: Microsoft Visual C++ 2008 SP1.
- Wireshark 1.0.x and earlier: Microsoft Visual C++ 6.0.

Using the release compilers is recommended for Wireshark development work.

“Community” editions of Visual Studio such as “Visual Studio Community 2017” can be used to compile Wireshark but any PortableApps packages you create with them might require the installation of a separate Visual C++ Redistributable package on any machine on which the PortableApps package is to be used. See Visual C++ Runtime “Redistributable” Files below for more details.

However, you might already have a different Microsoft C++ compiler installed. It should be possible to use any of the following with the considerations listed. You will need to sign up for a Visual Studio Dev Essentials account if you don't have a Visual Studio (MSDN) subscription. The older versions can be downloaded from https://visualstudio.microsoft.com/vs/older-downloads/.

Visual C++ 2015 Community Edition

**IDE + Debugger?**

Yes

**SDK required for 64-bit builds?**

No

CMake Generator: Visual Studio 14

You can use Chocolatey to install Visual Studio, e.g:
PS:\> choco install VisualStudioCommunity2015

**cl.exe (C Compiler)**

The following table gives an overview of the possible Microsoft toolchain variants and their specific C compiler versions ordered by release date.

<table>
<thead>
<tr>
<th>Compiler Package</th>
<th>cl.exe</th>
<th>_MSC_VER</th>
<th>CRT DLL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visual Studio 2015</td>
<td>14.0</td>
<td>1900</td>
<td>msvcr140.dll</td>
</tr>
</tbody>
</table>

After correct installation of the toolchain, typing at the Visual Studio Command line prompt (cmd.exe):

> cl

should result in something like:

```
Microsoft (R) C/{cpp} Optimizing Compiler Version 18.00.31101 for x86
Copyright (C) Microsoft Corporation. All rights reserved.

usage: cl [ option... ] filename... [ /link linkoption...]
```

However, the version string may vary.

Documentation on the compiler can be found at Microsoft Docs

**link.exe (Linker)**

After correct installation, typing at the Visual Studio Command line prompt (cmd.exe):

> link

should result in something like:

```
Microsoft (R) Incremental Linker Version 12.00.31101.0
Copyright (C) Microsoft Corporation. All rights reserved.

usage: LINK [options] [files] [@commandfile]
...
```
However, the version string may vary.

Documentation on the linker can be found at Microsoft Docs

**Visual C++ Runtime “Redistributable” Files**

Please note: The following is not legal advice. Ask your preferred lawyer instead. It's the authors view and this view might be wrong.

Wireshark and its libraries depend on POSIX functions such as fopen() and malloc(). On Windows, these functions are provided by the Microsoft Visual C++ Runtime. There are many different versions of the CRT and Visual C++ 2015 and later use the *Universal CRT*.

The Universal CRT comes standard with Windows 10 and is installed as part of Windows Update on earlier versions of Windows. The Wireshark .exe installers include redistributables (vcredist_x86.exe or vcredist_x64.exe) which ensure that the Universal CRT is installed and up to date.

**NOTE**

*Make sure you’re allowed to distribute this file*

The files to redistribute must be mentioned in the redist.txt file of the compiler package. Otherwise it can’t be legally redistributed by third parties like us.

The following Microsoft Docs link is recommended for the interested reader:

Redistributing Visual C++ Files

In all cases where vcredist_x86.exe or vcredist_x64.exe is downloaded it should be downloaded to the directory into which the support libraries for Wireshark have been downloaded and installed. This directory is specified by the WIRESHARK_BASE_DIR or WIRESHARK_LIB_DIR environment variables. It need not, and should not, be run after being downloaded.

**Windows Platform SDK**

The Windows Platform SDK (PSDK) or Windows SDK is a free (as in beer) download and contains platform specific headers and libraries (e.g. windows.h, WSock32.lib, etc.). As new Windows features evolve in time, updated SDKs become available that include new and updated APIs.

When you purchase a commercial Visual Studio or use the Community Edition, it will include an SDK.

**Documentation Toolchain**

Wireshark's documentation is split across two directories. The doc directory contains man pages written in Perl’s POD (Plain Old Documentation) format. The docbook directory contains the User’s Guide, Developer’s Guide, and the release notes, which are written in Asciidoctor markup.
Our various output formats are generated using the following tools. Intermediate formats are in *italics*.

**Guide HTML**

Asciidoctor → DocBook XML → xsltproc + DocBook XSL

**Guide PDF**

Asciidoctor

**Guide HTML Help**

Asciidoctor → DocBook XML → xsltproc + DocBook XSL → HHC

**Release notes HTML**

Asciidoctor

**Release notes text**

Asciidoctor → HTML → html2text.py

**Asciidoctor**

Asciidoctor comes in several flavors: a Ruby gem (Asciidoctor), a Java bundle (AsciidoctorJ), and transpiled JavaScript (Asciidoctor.js). Only the Asciidoctor and AsciidoctorJ flavors are supported for building the Wireshark documentation and AsciidoctorJ is recommended.

The guides and release notes were originally written in DocBook (hence the directory name). They were later converted to AsciiDoc and then migrated to Asciidoctor. `compat-mode` is currently enabled for the guides, but we are steadily migrating to Asciidoctor's modern (>= 1.5.0) syntax.

PDF output requires Asciidoctor PDF. It is included with AsciidoctorJ but not with Asciidoctor.

**Xsltproc And DocBook**

The single HTML, chunked HTML, and HTML Help guides are generated using DocBook XSL stylesheets. They in turn require an XSLT processor. We use `xsltproc`.

**HTML Help**

HTML Help is used to create the User's and Developer's Guide in .chm format. The User's Guide .chm file is included with the NSIS and WiX installers and is used as Wireshark's built-in help on Windows.

This compiler is used to generate a .chm file from a bunch of HTML files — in our case to generate the User's and Developer's Guide in .chm format.

The compiler is only available as the free (as in beer) "HTML Help Workshop" download. If you want to compile the guides yourself, you need to download and install this. If you don't install it
into the default directory, you may also have a look at the HHC_DIR setting in the file docbook/Makefile.

The files htmlhelp.c and htmlhelp.lib are required to be able to open .chm files from Wireshark and show the online help. Both files are part of the SDK (standalone (P)SDK or MSVC since 2002).

**Debugger**

Using a good debugger can save you a lot of development time.

The debugger you use must match the C compiler Wireshark was compiled with, otherwise the debugger will simply fail or you will only see a lot of garbage.

**Visual Studio Integrated Debugger**

You can use the integrated debugger of Visual Studio if your toolchain includes it. Open the solution in your build directory and build and debug as normal with a Visual Studio solution.

To set the correct paths for Visual Studio when running Wireshark under the debugger, add the build output directory to the path before opening Visual Studio from the same command prompt, e.g.

```
C:\Development\wsbuild32>set PATH="%PATH%;C:\Development\wsbuild32\run\RelWithDebInfo"
C:\Development\wsbuild32>wireshark.sln
```

for PowerShell use

```
PS C:\Development\wsbuild32>$env:PATH += ";(Convert-Path run\RelWithDebInfo)"
PS C:\Development\wsbuild32>wireshark.sln
```

When Visual Studio has finished loading the solution, set the executable to be run in the debugger, e.g. Executables\Wireshark, by right clicking it in the Solution Explorer window and selecting "Set as StartUp Project". Also set the Solution Configuration (usually RelWithDebInfo) from the droplist on the toolbar.

**NOTE**

Currently Visual Studio regards a command line build as incomplete, so will report that some items need to be built when starting the debugger. These can either be rebuilt or ignored as you wish.

The normal build is an optimised release version so debugging can be a bit difficult as variables are optimised out into registers and the execution order of statements can jump around.

If you require a non-optimised version, then build using a debug configuration.
Debugging Tools For Windows

You can also use the Microsoft Debugging Tools for Windows toolkit, which is a standalone GUI debugger. Although it's not that comfortable compared to debugging with the Visual Studio integrated debugger it can be helpful if you have to debug on a machine where an integrated debugger is not available.

You can get it free of charge from Microsoft in several ways, see the Debugging tools for Windows page.

You can also use Chocolatey to install WinDbg:

```
PS:\> choco install windbg
```

To debug Wireshark using WinDbg, open the built copy of Wireshark using the File → Open Executable… menu, i.e. C:\Development\wsbuild32\run\RelWithDebInfo\Wireshark.exe. To set a breakpoint open the required source file using the File → Open Source File… menu and then click on the required line and press F9. To run the program, press F5.

If you require a non-optimised version, then build using a debug configuration, e.g. `msbuild /m /p:Configuration=Debug Wireshark.sln`. The build products will be found in C:\Development\wsbuild32\run\Debug\.

bash

The bash shell is needed to run several shell scripts.

Unix

Bash (the GNU Bourne-Again SHell) is available for most UNIX and UNIX-like platforms. If it isn’t already installed or available as a package for your platform, you can get it at https://www.gnu.org/software/bash/bash.html.

After correct installation, typing at the bash command line prompt:

```
$ bash --version
```

should result in something like:

```
GNU bash, version 4.4.12(1)-release (x86_64-pc-linux-gnu)
Copyright (C) 2016 Free Software Foundation, Inc.
```

Your version string will likely vary.
Python

Python is an interpreted programming language. It is used to generate some source files, documentation, testing and other tasks. Python 3.4 and later is required. Python 2.7 is no longer supported.

Python is either included or available as a package on most UNIX-like platforms. Windows packages and source are available at https://python.org/download/.

You can also use Chocolatey to install Python:

```
PS:~> choco install Python3
```

Chocolatey installs Python into C:\Python37 by default. You can verify your Python version by running

```
$ python3 --version
```

on UNIX-like platforms and

```
rem Official package
C:> cd python35
C:Python35> python --version

rem Chocolatey
C:> cd \tools\python3
C:\tools\python3> python --version
```

on Windows. You should see something like

```
Python 3.5.1
```

Your version string may vary of course.

Perl

Perl is an interpreted programming language. The homepage of the Perl project is https://www.perl.org. Perl is used to convert various text files into usable source code. Perl version 5.6 and above should work fine.

Unix
Perl is available for most UNIX and UNIX-like platforms. If perl isn’t already installed or available as a package for your platform, you can get it at https://www.perl.org/.

After correct installation, typing at the bash command line prompt:

```
$ perl --version
```

should result in something like:

```
This is perl 5, version 26, subversion 0 (v5.26.0) built for x86_64-linux-gnu-thread-multi
(with 62 registered patches, see perl -V for more detail)

Copyright 1987-2017, Larry Wall

Perl may be copied only under the terms of either the Artistic License or the GNU General Public License, which may be found in the Perl 5 source kit.

Complete documentation for Perl, including FAQ lists, should be found on this system using "man perl" or "perldoc perl". If you have access to the Internet, point your browser at http://www.perl.org/, the Perl Home Page.
```

However, the version string may vary.

**Windows**

A native Windows Perl package can be obtained from Strawberry Perl or Active State. The installation should be straightforward.

You may also use Chocolatey to install either package:

```
PS:\> choco install StrawberryPerl
```

or

```
PS:\> choco install ActivePerl
```

After correct installation, typing at the command line prompt (cmd.exe):

```
> perl -v
```

should result in something like:
However, the version string may vary.

**Bison**

Bison is a parser generator used for some of Wireshark's file format support.

**Unix**

Bison is available for most UNIX and UNIX-like platforms. See the next section for native Windows options.

If GNU Bison isn't already installed or available as a package for your platform you can get it at: [https://www.gnu.org/software/bison/bison.html](https://www.gnu.org/software/bison/bison.html).

After correct installation running the following

```
$ bison --version
```

should result in something like:

```
bison (GNU Bison) 2.3
Written by Robert Corbett and Richard Stallman.

Copyright (C) 2006 Free Software Foundation, Inc.
This is free software; see the source for copying conditions. There is NO
warranty; not even for MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.
```

Your version string may vary.

**Windows**

A native Windows version of bison is available in the *winflexbison* Chocolatey package. Note that the executable is named *win_bison*.
Native packages are available from other sources such as GnuWin. They aren’t officially supported but should work.

**Flex**

Flex is a lexical analyzer generator used for Wireshark’s display filters, some file formats, and other features.

**Unix**

Flex is available for most UNIX and UNIX-like platforms. See the next section for native Windows options.

If GNU flex isn’t already installed or available as a package for your platform you can get it at https://www.gnu.org/software/flex/.

After correct installation running the following

```
$ flex --version
```

should result in something like:

```
flex version 2.5.4
```

Your version string may vary.

**Windows**

A native Windows version of flex is available in the winflexbison Chocolatey package. Note that the executable is named win_flex.

```
PS:\>choco install winflexbison
```

Native packages are available from other sources such as GnuWin. They aren’t officially supported but should work.

**Git client**

The Wireshark project uses its own Git repository to keep track of all the changes done to the source code. Details about the usage of Git in the Wireshark project can be found in The Wireshark Git repository.
If you want to work with the source code and are planning to commit your changes back to the Wireshark community, it is recommended to use a Git client to get the latest source files. For detailed information about the different ways to obtain the Wireshark sources, see Obtain the Wireshark sources.

You will find more instructions in Git over SSH or HTTPS on how to use the Git client.

**Unix**

Git is available for most UNIX and UNIX-like platforms. If Git isn't already installed or available as a package for your platform, you can get it at: https://git-scm.com/.

After correct installation, typing at the bash command line prompt:

```
$ git --version
```

should result in something like:

```
git version 2.14.1
```

Your version will likely be different.

**Windows**

The Git command line tools for Windows can be found at https://git-scm.com/download/win and can also be installed using Chocolatey:

```
PS:>
```

After correct installation, typing at the command line prompt (cmd.exe):

```
> git --version
```

should result in something like:

```
git version 2.16.1.windows.1
```

However, the version string may vary.
Git Powershell Extensions (Optional)

A useful tool for command line git on Windows is PoshGit. Poshgit provides git command completion and alters the prompt to indicate the local working copy status. You can install it using Chocolatey:

```
PS:\>choco install poshgit
```

Git GUI Client (Optional)

Along with the traditional command-line client, several GUI clients are available for a number of platforms. See [https://git-scm.com/downloads/guis](https://git-scm.com/downloads/guis) for details.

patch (Optional)

The patch utility is used to merge a diff file into your own source tree. This tool is only needed, if you want to apply a patch (diff file) from someone else (probably from the developer mailing list) to try out in your own private source tree.

It most cases you may not need the patch tool installed. Git and Gerrit should handle patches for you.

You will find more instructions in [Apply a patch from someone else](https://git-scm.com/docs/apply-patch) on how to use the patch tool.

Unix

Patch is available for most UNIX and UNIX-like platforms. If GNU patch isn't already installed or available as a package for your platform, you can get it at [https://www.gnu.org/software/patch/patch.html](https://www.gnu.org/software/patch/patch.html).

After correct installation, typing at the bash command line prompt:

```
$ patch --version
```

should result in something like:
Windows

The Windows native Git tools provide patch. A native Windows patch package can be obtained from [http://gnuwin32.sourceforge.net/](http://gnuwin32.sourceforge.net/). The installation should be straightforward.

Windows: NSIS (Optional)

The NSIS (Nullsoft Scriptable Install System) is used to generate `Wireshark-win32-3.1.1.exe` from all the files needed to be installed, including all required DLLs, plugins, and supporting files.

To install it, download the latest released version from [https://nsis.sourceforge.net](https://nsis.sourceforge.net). NSIS v3 is required. You can also install it using Chocolatey:

```
PS$> choco install nsis
```

You can find more instructions on using NSIS in [Windows: NSIS.exe Installer](#).

Windows: WiX Toolset (Optional)

The WiX Toolset can be used to generate Windows Installer (.msi) packages. You can download it from the [WiX web site](#) or install it using Chocolatey:

```
PS$> choco install wixtoolset
```

Wireshark's .msi packaging is currently experimental and the generated packages may be incomplete.
**Windows: PortableApps (Optional)**

The PortableApps.com Installer is used to generate *WiresharkPortable-3.1.1.paf.exe* from all the files needed to be installed, including all required DLLs, plugins, and supporting files.

To install it, do the following:

- Download the latest PortableApps.com Platform release from https://portableapps.com/.
- Install the following applications in the PortableApps.com environment:
  - PortableApps.com Installer
  - PortableApps.com Launcher
  - NSIS Portable (Unicode)
  - PortableApps.com AppCompactor

You can find more instructions on using the PortableApps.com Installer in *Windows: PortableApps .paf.exe Package*.
Library Reference

Introduction

Several libraries are needed to build and run Wireshark. Most of them are split into three packages:

1. *Runtime.* System and third party libraries such as *vcruntime140.dll* and *libglib-2.0-0.dll.*
2. *Developer.* Documentation, header files, import libraries, and other files needed for compilation.
3. *Source.* Library sources, which are usually not required to build Wireshark.

**TIP**

Our libraries are freely available

Binary Library Formats

Binary libraries are available in different formats, depending on the C compiler used to build it and of course the platform they were built for.

**Unix**

If you have installed unix binary libraries on your system, they will match the C compiler. If not already installed, the libraries should be available as a package from the platform installer, or you can download and compile the source and then install the binaries.

**Windows**

Most of the Win32 binary libraries you will find on the web are in this format. You will recognize MSVC libraries by the .lib/.dll file extension.

Windows Automated Library Download

The required libraries (apart from Qt) are automatically downloaded as part of the CMake generation step, and subsequently as required when libraries are updated.

The libraries are downloaded into the directory indicated by the environment variable `WIRESHARK_BASE_DIR`, this must be set appropriately for your environment. The libraries are downloaded and extracted into `WIRESHARK_BASE_DIR\wireshark-win32-libs` and `WIRESHARK_BASE_DIR\wireshark-win64-libs` for 32 and 64 bit builds respectively.

You may also directly set the library directory with the environment variable ...
WIRESHARK_LIB_DIR, but if you switch between 32 bit and 64 bit builds, the value of this must be set appropriately.

Qt

The Qt library is used to build the UI for Wireshark and is used to provide a platform independent UI. Wireshark can be built with Qt 5.2 or later.

For more information on the Qt libraries, see The Qt Application Framework.

Unix

Most Linux distributions provide Qt and its development libraries as standard packages. The required libraries and tools will likely be split across several packages. For example, building on Ubuntu requires qttools5-dev, qttools5-dev-tools, libqt5svg5-dev, qtmultimedia5-dev, and possibly others.

The Qt Project provides an installation tool for macOS, similar to Windows. It is available at https://www.qt.io/download-open-source/#section-2.

Windows

Qt5 must be installed manually from the Qt installers page https://www.qt.io/download-open-source/#section-2 using the version of Qt appropriate for your compiler. Note that separate installations (into different directories) of Qt are required for 32 bit and 64 bit builds. The environment variable QT5_BASE_DIR should be set as appropriate for your environment and should point to the Qt directory that contains the bin directory, e.g. C:\Qt\5.9.5\msvc2017_64.

GLib And Supporting Libraries

The GLib library is used as a basic platform abstraction library and can be used in both CLI and GUI applications. For a detailed description about GLib see The GLib library.

GLib depends on GNU libiconv, GNU gettext, and other libraries. You will typically not come into contact with these while doing Wireshark development. Wireshark’s build system check for and require both GLib and its dependencies.

Unix

The GLib library is available for most Linux distributions and UNIX flavors. If it isn’t already installed and isn’t available as a package for your platform, you can get it at https://wiki.gnome.org/Projects/GLib.

Windows

**SMI (Optional)**

LibSMI is used for MIB and PIB parsing and for OID resolution.

**Unix**

If this library isn’t already installed or available as a package for your platform, you can get it at https://www.ibr.cs.tu-bs.de/projects/libsmi/.

**Windows**

**c-ares (Optional)**

C-Ares is used for asynchronous DNS resolution. This is the primary name resolution library in Wireshark.

**Unix**

If this library isn’t already installed or available as a package for your platform, you can get it at https://c-ares.haxx.se/.

**Windows**

C-Ares is cross-compiled using MinGW32 and is available at https://anonsvn.wireshark.org/wireshark-win32-libs/trunk/packages/.

**zlib (Optional)**

zlib is designed to be a free, general-purpose, legally unencumbered — that is, not covered by any patents — lossless data-compression library for use on virtually any computer hardware and operating system.

— The zlib web site, https://www.zlib.net/

**Unix**

This library is almost certain to be installed on your system. If it isn’t or you don’t want to use the
default library you can download it from https://www.zlib.net/.

**Windows**

The zlib sources are downloaded from https://anonsvn.wireshark.org/wireshark-win32-libs/trunk/packages/ and compiled locally.

**libpcap or Npcap (Optional, But Strongly Recommended)**

Libpcap and Npcap provide that packet capture capabilities that are central to Wireshark's core functionality.

**Unix: libpcap**

If this library isn’t already installed or available as a package for your platform, you can get it at https://www.tcpdump.org/.

**Windows: Npcap**

The Windows build environment compiles and links against the WinPcap SDK (WpdPack) and includes the Npcap packet capture driver with the .exe installer. Both are automatically downloaded by CMake.

You can download the Npcap Windows packet capture library manually from https://nmap.org/npcap/.

**WARNING**

Npcap has its own license with its own restrictions

Insecure.Com LLC, aka “The Nmap Project” has granted the Wireshark Foundation the right to include Npcap with the installers that we distribute from wireshark.org. If you wish to distribute your own Wireshark installer or any other package that includes Npcap you must comply with the Npcap license and may be required to purchase a redistribution license. Please see https://nmap.org/npcap/ for more details.

**GnuTLS (Optional)**

The GNU Transport Layer Security Library is used to enable TLS decryption using an RSA private key.

**Unix**

If this library isn’t already installed or available as a package for your platform, you can get it at https://gnutls.org/.
**Windows**

We provide a package cross-compiled using MinGW32 at [https://anonsvn.wireshark.org/wireshark-win32-libs/trunk/packages/](https://anonsvn.wireshark.org/wireshark-win32-libs/trunk/packages/).

**Gcrypt**

The Gcrypt Library is a low-level cryptographic library that provides support for many ciphers and message authentication codes, such as DES, 3DES, AES, Blowfish, SHA-1, SHA-256, and others.

**Unix**

If this library isn’t already installed or available as a package for your platform, you can get it at [https://directory.fsf.org/wiki/Libgcrypt](https://directory.fsf.org/wiki/Libgcrypt).

**Windows**

Part of our GnuTLS package.

**Kerberos (Optional)**

The Kerberos library is used to dissect Kerberos, sealed DCERPC and secureLDAP protocols.

**Unix**

If this library isn’t already installed or available as a package for your platform, you can get it at [https://web.mit.edu/Kerberos/dist/](https://web.mit.edu/Kerberos/dist/).

**Windows**

We provide a package at [https://anonsvn.wireshark.org/wireshark-win32-libs/trunk/packages/](https://anonsvn.wireshark.org/wireshark-win32-libs/trunk/packages/).

**LUA (Optional)**

The LUA library is used to add scripting support to Wireshark.

**Unix**

If this library isn’t already installed or available as a package for your platform, you can get it at [https://www.lua.org/download.html](https://www.lua.org/download.html).

**Windows**

We provide a copy of the official package at [https://anonsvn.wireshark.org/wireshark-win32-libs/trunk/packages/](https://anonsvn.wireshark.org/wireshark-win32-libs/trunk/packages/).
MaxMindDB (Optional)

MaxMind Inc. publishes a set of IP geolocation databases and related open source libraries. They can be used to map IP addresses to geographical locations and other information.

If libmaxminddb library isn't already installed or available as a package for your platform, you can get it at https://github.com/maxmind/libmaxminddb.

We provide a package for Windows at https://anonsvn.wireshark.org/wireshark-win32-libs/trunk/packages/.

WinSparkle (Optional)

WinSparkle is an easy-to-use software update library for Windows developers.

Windows

We provide a copy of the WinSparkle package at https://anonsvn.wireshark.org/wireshark-win32-libs/trunk/packages/.
Wireshark Development

Wireshark Development

The second part describes how the Wireshark sources are structured and how to change the sources such as adding a new dissector.
How Wireshark Works

Introduction

This chapter will give you a short overview of how Wireshark works.

Overview

The following will give you a simplified overview of Wireshark's function blocks:
Figure 1. Wireshark function blocks

The function blocks in more detail:

**GUI**

Handling of all user input/output (all windows, dialogs and such). Source code can be found in
the `ui/qt` directory.

**Core**

Main "glue code" that holds the other blocks together. Source code can be found in the root directory.

**Epan**

Enhanced Packet ANalyzer — the packet analyzing engine. Source code can be found in the `epan` directory. Epan provides the following APIs:

- Protocol Tree. Dissection information for an individual packet.
- Dissectors. The various protocol dissectors in `epan/dissectors`.
- Dissector Plugins - Support for implementing dissectors as separate modules. Source code can be found in `plugins`.
- Display Filters - The display filter engine at `epan/dfilter`.

**Wiretap**

The wiretap library is used to read and write capture files in `libpcap`, `pcapng`, and many other file formats. Source code is in the `wiretap` directory.

**Capture**

The interface with the capture engine. Source code is in the root directory.

**Dumpcap**

The capture engine itself. This is the only part that is to execute with elevated privileges. Source code is in the root directory.

**Npcap and libpcap**

These are separate libraries that provide packet capture and filtering support on different platforms. The filtering in Npcap and libpcap works at a much lower level than Wireshark's display filters and uses a significantly different mechanism. That's why we have different display and capture filter syntaxes.

**Capturing packets**

Capturing takes packets from a network adapter and saves them to a file on your hard disk.

Since raw network adapter access requires elevated privileges these functions are isolated into the `dumpcap` program. It's only this program that needs these privileges, allowing the main part of the code (dissectors, user interface, etc) to run with normal user privileges.

To hide all the low-level machine dependent details from Wireshark, the `libpcap` and `Npcap` (see `libpcap` or `Npcap` (Optional, But Strongly Recommended)) libraries are used. These libraries provide a general purpose interface to capture packets and are used by a wide variety of applications.
Capture Files

Wireshark can read and write capture files in its natural file formats, pcapng and pcap, which are used by many other network capturing tools, such as tcpdump. In addition to this, as one of its strengths, Wireshark can read and write files in many different file formats of other network capturing tools. The wiretap library, developed together with Wireshark, provides a general purpose interface to read and write all the file formats. If you need to add support for another capture file format this is the place to start.

Dissect packets

While Wireshark is loading packets from a file each packet is dissected. Wireshark tries to detect the packet type and gets as much information from the packet as possible. In this run though, only the information shown in the packet list pane is needed.

As the user selects a specific packet in the packet list pane this packet will be dissected again. This time, Wireshark tries to get every single piece of information and put it into the packet details pane.
Introduction

Source overview

Wireshark consists of the following major parts:

- Packet dissection - in the /epan/dissectors and /plugins/epan/* directories
- Capture file I/O - using Wireshark's own wiretap library
- Capture - using the libpcap and Npcap libraries, in dumpcap.c and the /capchild and /caputils directories
- User interface - using Qt and associated libraries
- Utilities - miscellaneous helper code
- Help - using an external web browser and text output

Coding Style

The coding style guides for Wireshark can be found in the "Code style" section of the file doc/README.developer.

The GLib library

GLib is used as a basic platform abstraction library. It doesn’t provide any direct GUI functionality.

To quote the GLib Reference Manual:

GLib provides the core application building blocks for libraries and applications written in C. It provides the core object system used in GNOME, the main loop implementation, and a large set of utility functions for strings and common data structures.

Packet Capture

This chapter needs to be reviewed and extended.

How To Add A New Capture Type To Libpcap

For this discussion, I’ll assume you’re working with libpcap 1.0 or later. You probably don’t want to work with a version older than 1.0, even if whatever OS you’re using happens to include libpcap - older versions are not as friendly towards adding support for devices other than standard network interfaces.

First, read the libpcap documentation on writing a new libpcap module

(It’s currently incomplete, but I’ll be finishing it up over time. If you have contributions, feel free to submit pull requests for it.)

If you had to introduce one or more new DLT_* values, you will also have to add support in Wireshark for those DLT_* values to wiretap/pcap-common.c, which might mean adding one or more WTAP_ENCAP types to wtap.h and to the encap_table[] table in wiretap/wtap.c. You’d then have to write a dissector or dissectors for the link-layer protocols or protocols and have them register themselves with the wtap_encap dissector table, with the appropriate WTAP_ENCAP values by calling dissector_add_uint().

Extcap: Developer Guide

The extcap interface is a versatile plugin interface that allows external binaries to act as capture interfaces directly in Wireshark. It is used in scenarios, where the source of the capture is not a traditional capture model (live capture from an interface, from a pipe, from a file, etc). The typical example is connecting esoteric hardware of some kind to the main Wireshark app.

Without extcap, a capture can always be achieved by directly writing to a capture file:

*Bash example for traditional capture with a capture file.*

```bash
$ the-esoteric-binary --the-strange-flag --interface=stream1 --file dumpfile.pcap &
$ wireshark dumpfile.pcap
```

but the extcap interface allows for such a connection to be easily established and configured using the Wireshark GUI.

The extcap subsystem is made of multiple extcap binaries that are automatically called by the GUI in a row. In the following chapters we will refer to them as "the extcaps".
Extcaps may be any binary or script within the extcap directory. Please note, that scripts need to be executable without prefacing a script interpreter before the call.

**IMPORTANT**

**Windows Users** Because of restrictions directly calling the script may not always work. In such a case, a batch file may be provided, which then in turn executes the script. Please refer to [Execute a script-based extcap on Windows](#) for more information.

When Wireshark launches an extcap, it automatically adds its installation path (c:\Program Files\Wireshark) to the DLL search path so that the extcap library dependencies can be found (it is not designed to be launched by hand). This is done on purpose. There should only be extcap programs (executable, python scripts, ...) in the extcap folder to reduce the startup time and not have Wireshark trying to execute other file types.

**Extcap command line interface**

The actual capture is run after a setup process that can be made manually by the user or automatically by the GUI. All the steps performed are done for every extcap.

Let's go through those steps.

**Query for available interfaces**

In the first step the extcap is queried for its interfaces.

```
$ extcapbin --extcap-interfaces
```

This call must print the existing interfaces for this extcap and must return 0. The output must conform to the grammar specified for extcap, and it is specified in the doc/extcap.4 generated man page (in the build dir).

Since Wireshark 2.9 this call is extended with `--extcap-version=x.x`, which will always represent the calling Wireshark's version information. This can be used to change behavior depending on the Wireshark version in question.

**Example call for interface query**

```
$ extcap_example.py --extcap-interfaces --extcap-version=3.0
extcap {version=1.0}{help=Some help url}
  interface {value=example1}{display=Example interface 1 for extcap}
  interface {value=example2}{display=Example interface 2 for extcap}
```

The **version** for the extcap sentence (which may exist as many times as is needed, but only the last one will be used) will be used for displaying the version information of the extcap interface in the about dialog of Wireshark.
The value for each interface will be used in subsequent calls as the interface name IFACE.

Using the help argument, an interface may provide a generic help URL for the extcap utility.

**Ask for DLT’s to each interface**

The extcap binary is queried for all valid DLTs for all the interfaces returned by step 1.

```
$ extcap_example.py --extcap-dlts --extcap-interface IFACE
```

This call must print the valid DLTs for the interface specified. This call is made for all the interfaces and must return 0.

**Example for the DLT query**

```
$ extcap_example.py --extcap-interface IFACE --extcap-dlts
dlt {number=147}{name=USER1}{display=Demo Implementation for Extcap}
```

A binary or script, which neither provides an interface list or a DLT list will not show up in the extcap interfaces list.

**The extcap configuration interface**

The extcap binary is asked for the configuration of a specific interface.

```
$ extcap_example.py --extcap-interface IFACE --extcap-config
```

Each interface can have custom options that are valid for this interface only. Those config options are specified on the command line when running the actual capture. To allow an end-user to specify certain options, such options may be provided using the extcap config argument.

To share which options are available for an interface, the extcap responds to the command `--extcap-config`, that shows all the available options (aka additional command line options).

Those options are automatically presented via a dialog to the user for the individual interface.
Example for interface options

```
$ extcap_example.py --extcap-interface IFACE --extcap-config
arg {number=0}{call=--delay}{display=Time delay}{tooltip=Time delay between packages}{type=Integer}{range=1,15}{required=true}
arg {number=1}{call=--message}{display=Message}{tooltip=Package message content}{placeholder=Please enter a message here ...}{type=String}
arg {number=2}{call=--verify}{display=Verify}{tooltip=Verify package content}{type=boolflag}
arg {number=3}{call=--remote}{display=Remote Channel}{tooltip=Remote Channel Selector}{type=selector}
arg {number=4}{call=--server}{display=IP address for log server}{type=string}{validation=\b(?:25[0-5]|2[0-4]\[0-9]|1\[0-9][0-9]|0\.?\d\d\d)\.\b{3}(?:25[0-5]|2[0-4]\[0-9]|1\[0-9][0-9]|0\.?\d\d\d)\b}
value {arg=3}{value=if1}{display=Remote1}{default=true}
value {arg=3}{value=if2}{display=Remote2}{default=false}
```

Now the user can click on the options and change them. They are sent to the extcap when the capture is launched.

There are three kind of options available:

**Flag**
- boolflag for instance expects the option to be present resulting in the corresponding entry set to true, false otherwise

**Value**
- are value based options and each expect a single value via the command-line call

**Selection**
- are selections and can be presented multiple times in the command line. Both expect subsequent "value" items in the config list, with the corresponding argument selected via arg

**The capture process**

Once the interfaces are listed and configuration is customized by the user the capture is started.

```
$ extcap_example.py --extcap-interface IFACE [params] --capture [--extcap-capture-filter CFILTER]
--fifo FIFO
```

To run the capture, the extcap must implement the **--capture, --extcap-capture-filter** and **--fifo** option.

They are automatically added by Wireshark that opens the fifo for reading. All the other options
are automatically added to run the capture. The extcap interface is used like all other interfaces (meaning that capture on multiple interfaces, as well as stopping and restarting the capture is supported).

**Execute a script-based extcap on Windows**

To use scripts on Windows, please generate an `<scriptname>.bat` inside the extcap folder, with the following content (in this case for a Python-based extcap utility):

```
@echo off
<Path to python interpreter> <Path to script file> %*
```

Windows is not able to execute most scripts directly (Powershell being an exception), which also goes for all other script-based formats besides VBScript and PowerShell

**Extcap Arguments**

The extcap interface provides the possibility for generating a GUI dialog to set and adapt settings for the extcap binary.

All options must provide a number, by which they are identified. No NUMBER may be provided twice. Also all options must present the elements CALL and DISPLAY, where call provides the arguments name on the command-line and display the name in the GUI.

Additionally TOOLIP and PLACEHOLDER may be provided, which will give the user an explanation within the GUI, about what to enter into this field.

These options do have types, for which the following types are being supported:

**INTEGER, UNSIGNED, LONG, DOUBLE**

This provides a field for entering a numeric value of the given data type. A DEFAULT value may be provided, as well as a RANGE

```
arg {number=0}{call=--delay}{display=Time delay}{tooltip=Time delay between packages}{type=integer}{range=1,15}{default=0}
```

**STRING**

Let the user provide a string to the capture

```
arg {number=1}{call=--server}{display=IP Address}{tooltip=IP Address for log server}{type=string}{validation=\b(?:25[0-5]|2[0-4][0-9]|10[0-9]|0[0-99])\.){3}(?:25[0-5]|2[0-4][0-9]|10[0-9]|0[0-99])\b
```
**validation** allows to provide a regular expression string, which is used to check the user input for validity beyond normal data type or range checks. Backslashes must be escaped (as in `\b` for `\b`)

**PASSWORD**

Let the user provide a masked string to the capture. Password strings are not saved, when the extcap configuration is being saved

```arg {number=0}{call=--password}{display=The user password}{tooltip=The password for the connection}{type=password}
```

**BOOLEAN, BOOLFLAG**

This provides the possibility to set a true/false value. BOOLFLAG values will only appear in the command-line if set to true, otherwise they will not be added to the command-line call for the extcap interface

```arg {number=2}{call=--verify}{display=Verify}{tooltip=Verify package content}{type=boolflag}
```

**FILESELECT**

Let the user provide a filepath to the capture. If MUSTEXIST is being provided, the GUI checks if the file exists.

```arg {number=3}{call=--logfile}{display=Logfile}{tooltip=A file for log messages}{type=fileselect}{mustexist=false}
```

**SELECTOR, RADIO, MULTICHECK**

Optionfields, where the user may choose one or more options from. If PARENT is provided for the value items, the option fields for MULTICHECK and SELECTOR are being presented in a tree-like structure. SELECTOR and RADIO values must present a default value, which will be the value provided to the extcap binary for this argument

```arg {number=3}{call=--remote}{display=Remote Channel}{tooltip=Remote Channel Selector}
value {arg=3}{value=if1}{display=Remote1}{default=true}
value {arg=3}{value=if2}{display=Remote2}{default=false}
```

**Reload a selector**

A selector may be reloaded from the configuration dialog of the extcap application within Wireshark. With the reload argument (defaults to false), the entry can be marked as reloadable.
Arg {number=3}{call=--remote}{display=Remote Channel}{tooltip=Remote Channel Selector}{type=selector}{reload=true}{placeholder=Load interfaces...}

After this has been defined, the user will get a button displayed in the configuration dialog for this extcap application, with the text "Load interfaces..." in this case, and a generic "Reload" text if no text has been provided.

The extcap utility is then called again with all filled out arguments and the additional parameter --extcap-reload-option <option_name>. It is expected to return a value section for this option, as it would during normal configuration. The provided option list is then presented as the selection, a previous selected option will be reselected if applicable.

Validation of arguments

Arguments may be set with {required=true} which enforces a value being provided, before a capture can be started using the extcap options dialog. This is not being checked, if the extcap is started via a simple double-click. The necessary fields are marked for the customer, to ensure a visibility for the end customer of the required argument.

Additionally text and number arguments may also be checked using a regular expression, which is provided using the validation attribute (see example above). The syntax for such a check is the same as for Qt RegExp classes. This feature is only active in the Qt version of Wireshark.

Toolbar Controls

An extcap utility can provide configuration for controls to use in an interface toolbar. These controls are bidirectional and can be used to control the extcap utility while capturing.

This is useful in scenarios where configuration can be done based on findings in the capture process, setting temporary values or give other inputs without restarting the current capture.
Example of interface definition with toolbar controls

```
$ extcap_example.py --extcap-interfaces
extcap {version=1.0}{display=Example extcap interface}
interface {value=example1}{display=Example interface 1 for extcap}
interface {value=example2}{display=Example interface 2 for extcap}
control {number=0}{type=string}{display=Message}{tooltip=Package message content. Must start with a capital letter.}{validation=[A-Z]+}{required=true}
control {number=1}{type=selector}{display=Time delay}{tooltip=Time delay between packages}
control {number=2}{type=boolean}{display=Verify}{default=true}{tooltip=Verify package content}
control {number=3}{type=button}{display=Turn on}{tooltip=Turn on or off}
control {number=4}{type=button}{role=logger}{display=Log}{tooltip=Show capture log}
value {control=1}{value=1}{display=1 sec}
value {control=1}{value=2}{display=2 sec}{default=true}
```

All controls will be presented as GUI elements in a toolbar specific to the extcap utility. The extcap must not rely on using those controls (they are optional) because of other capturing tools not using GUI (e.g. tshark, tfshark).

**Controls**

The controls are similar to the ARGUMENTS, but without the CALL element. All controls may be given a default value at startup and most can be changed during capture, both by the extcap and the user (depending on the type of control).

All controls must provide a NUMBER, by which they are identified. No NUMBER may be provided twice. Also all options must present the elements TYPE and DISPLAY, where TYPE provides the type of control to add to the toolbar and DISPLAY the name in the GUI.

Additionally TOOLTIP and PLACEHOLDER may be provided, which will give the user an explanation within the GUI.

All controls, except from the logger, help and restore buttons, may be disabled (and enabled) in GUI by the extcap during capture. This can be because of set-once operations, or operations which takes some time to complete.

All control values which are changed by the user (not equal to the default value) will be sent to the extcap utility when starting a capture. The extcap utility may choose to discard initial values and set new values, depending on implementation.

These TYPEs are defined as controls:

**BOOLEAN**

This provides a checkbox with the possibility to set a true/false value.
The extcap utility can set a default value at startup, and can change (set) and receive value changes while capturing. When starting a capture the GUI will send the value if different from the default value.

The payload is one byte with binary value 0 or 1.

Valid Commands: Set value, Enable, Disable.

**BUTTON**
This provides a button with different ROLES:

**CONTROL**
This button will send a signal when pressed. This is the default if no role is configured. The button is only enabled when capturing.

The extcap utility can set the button text at startup, and can change (set) the button text and receive button press signals while capturing. The button is disabled and the button text is restored to the default text when not capturing.

The payload is either the button text or empty (signal).

Valid Commands: Set value, Enable, Disable.

**LOGGER**
This provides a logger mechanism where the extcap utility can send log entries to be presented in a log window. This communication is unidirectional.

The payload is the log entry, and should be ended with a newline. Maximum length is 65535 bytes.

Valid Commands: Set log entry, Add log entry.

The Set command will clear the log before adding the entry.

**HELP**
This button opens the help page, if configured. This role has no controls and will not be used in communication.

Valid Commands: NONE.

**RESTORE**
This button will restore all control values to default. This role has no controls and will not be used in communication. The button is only enabled when not capturing.

Valid Commands: NONE.

**SELECTOR**
This provides a combo box with fixed values which can be selected.

The extcap utility can set default values at startup, and add and remove values and receive change in value selection while capturing. When starting a capture the GUI will send the value if different from the default value.

The payload is a string with the value, and optionally a string with a display value if this is different from the value. This two string values are separated by a null character.

Valid Commands: Set selected value, Add value, Remove value, Enable, Disable.

If value is empty the Remove command will remove all entries.

**STRING**

This provides a text edit line with the possibility to set a string or any value which can be represented in a string (integer, float, date, etc.).

The extcap utility can set a default string value at startup, and can change (set) and receive value changes while capturing. When starting a capture the GUI will send the value if different from the default value.

The payload is a string with the value. Maximum length is 32767 bytes.

Valid Commands for control: Set value, Enable, Disable.

The element VALIDATION allows to provide a regular expression string, which is used to check the user input for validity beyond normal data type or range checks. Backslashes must be escaped (as in `\b` for `\b`).

**Messages**

In addition to the controls it's possible to send a single message from the extcap utility to the user. This message can be put in the status bar or displayed in a information, warning or error dialog which must be accepted by the user. This message does not use the NUMBER argument so this can have any value.

**Control Protocol**

The protocol used to communicate over the control pipes has a fixed size header of 6 bytes and a payload with 0 - 65535 bytes.

*Table 3. Control packet:*

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sync Pipe Indication</td>
<td>(1 byte)</td>
</tr>
<tr>
<td>Message Length</td>
<td>(3 bytes network order)</td>
</tr>
<tr>
<td>Control Number</td>
<td>(1 byte)</td>
</tr>
<tr>
<td>Command</td>
<td>(1 byte)</td>
</tr>
</tbody>
</table>
Sync Pipe Indication:

The common sync pipe indication. This protocol uses the value “T”.

Message Length:

Payload length + 2 bytes for control number and command.

Control Number:

Unique number to identify the control. This number also gives the order of the controls in the interface toolbar.

Table 4. Commands and application for controls

<table>
<thead>
<tr>
<th>Command Byte</th>
<th>Command Name</th>
<th>Control type</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Initialized</td>
<td>none</td>
</tr>
<tr>
<td>1</td>
<td>Set</td>
<td>boolean / button / logger / selector / string</td>
</tr>
<tr>
<td>2</td>
<td>Add</td>
<td>logger / selector</td>
</tr>
<tr>
<td>3</td>
<td>Remove</td>
<td>selector</td>
</tr>
<tr>
<td>4</td>
<td>Enable</td>
<td>boolean / button / selector / string</td>
</tr>
<tr>
<td>5</td>
<td>Disable</td>
<td>boolean / button / selector / string</td>
</tr>
<tr>
<td>6</td>
<td>StatusBar message</td>
<td>none</td>
</tr>
<tr>

<td>none</td>
</tr>
<tr>
<td>8</td>
<td>Warning message</td>
<td>none</td>
</tr>
<tr>
<td>9</td>
<td>Error message</td>
<td>none</td>
</tr>
</tbody>
</table>

The Initialized command will be sent from the GUI to the extcap utility when all user changed control values are sent after starting a capture. This is an indication that the GUI is ready to receive control values.

The GUI will only send Initialized and Set commands. The extcap utility shall not send the Initialized command.

Messages with unknown control number or command will be silently ignored.
Packet dissection

How it works

Each dissector decodes its part of the protocol, and then hands off decoding to subsequent dissectors for an encapsulated protocol.

Every dissection starts with the Frame dissector which dissects the packet details of the capture file itself (e.g. timestamps). From there it passes the data on to the lowest-level data dissector, e.g. the Ethernet dissector for the Ethernet header. The payload is then passed on to the next dissector (e.g. IP) and so on. At each stage, details of the packet will be decoded and displayed.

Dissection can be implemented in two possible ways. One is to have a dissector module compiled into the main program, which means it’s always available. Another way is to make a plugin (a shared library or DLL) that registers itself to handle dissection.

There is little difference in having your dissector as either a plugin or built-in. On the Windows platform you have limited function access through the ABI exposed by functions declared as WS_DLL_PUBLIC.

The big plus is that your rebuild cycle for a plugin is much shorter than for a built-in one. So starting with a plugin makes initial development simpler, while the finished code may make more sense as a built-in dissector.

NOTE
Read README.dissector

The file doc/README.dissector contains detailed information about implementing a dissector. In many cases it is more up to date than this document.

Adding a basic dissector

Let’s step through adding a basic dissector. We’ll start with the made up “foo” protocol. It consists of the following basic items.

• A packet type - 8 bits, possible values: 1 - initialisation, 2 - terminate, 3 - data.
• A set of flags stored in 8 bits, 0x01 - start packet, 0x02 - end packet, 0x04 - priority packet.
• A sequence number - 16 bits.
• An IPv4 address.

Setting up the dissector

The first decision you need to make is if this dissector will be a built-in dissector, included in the main program, or a plugin.
Plugins are the easiest to write initially, so let’s start with that. With a little care, the plugin can be made to run as a built-in easily too so we haven’t lost anything.

**Example 1. Dissector Initialisation.**

```c
#include "config.h"
#include <epan/packet.h>
#define FOO_PORT 1234

static int proto_foo = -1;

void
proto_register_foo(void)
{
    proto_foo = proto_register_protocol(
        "FOO Protocol", /* name     */
        "FOO",     /* short name */
        "foo"      /* abbrev    */
    );
}
```

Let’s go through this a bit at a time. First we have some boilerplate include files. These will be pretty constant to start with.

Next we have an int that is initialised to `-1` that records our protocol. This will get updated when we register this dissector with the main program. It’s good practice to make all variables and functions that aren’t exported static to keep name space pollution down. Normally this isn’t a problem unless your dissector gets so big it has to span multiple files.

Then a `#define` for the UDP port that carries `foo` traffic.

Now that we have the basics in place to interact with the main program, we’ll start with two protocol dissector setup functions.

First we’ll call `proto_register_protocol()` which registers the protocol. We can give it three names that will be used for display in various places. The full and short name are used in e.g. the "Preferences" and "Enabled protocols" dialogs as well as the generated field name list in the documentation. The abbreviation is used as the display filter name.

Next we need a handoff routine.
Example 2. Dissector Handoff.

```c
void
proto_reg_handoff_foo(void)
{
    static dissector_handle_t foo_handle;

    foo_handle = create_dissector_handle(dissect_foo, proto_foo);
    dissector_add_uint("udp.port", FOO_PORT, foo_handle);
}
```

What’s happening here? We are initialising the dissector. First we create a dissector handle; It is associated with the foo protocol and with a routine to be called to do the actual dissecting. Then we associate the handle with a UDP port number so that the main program will know to call us when it gets UDP traffic on that port.

The standard Wireshark dissector convention is to put `proto_register_foo()` and `proto_reg_handoff_foo()` as the last two functions in the dissector source.

Now at last we get to write some dissecting code. For the moment we’ll leave it as a basic placeholder.

Example 3. Dissection.

```c
static int
dissect_foo(tvbuff_t *tvb, packet_info *pinfo, proto_tree *tree _U_, void *data _U_)
{
    col_set_str(pinfo->cinfo, COL_PROTOCOL, "FOO");
    /* Clear out stuff in the info column */
    col_clear(pinfo->cinfo,COL_INFO);

    return tvb_captured_length(tvb);
}
```

This function is called to dissect the packets presented to it. The packet data is held in a special buffer referenced here as tvb. We shall become fairly familiar with this as we get deeper into the details of the protocol. The packet info structure contains general data about the protocol, and we can update information here. The tree parameter is where the detail dissection takes place.

For now we’ll do the minimum we can get away with. In the first line we set the text of this to our protocol, so everyone can see it’s being recognised. The only other thing we do is to clear out any data in the INFO column if it’s being displayed.
At this point we should have a basic dissector ready to compile and install. It doesn’t do much at present, other than identify the protocol and label it.

In order to compile this dissector and create a plugin a couple of support files are required, besides the dissector source in `packet-foo.c`:

- *CMakeLists.txt* - Contains the CMake file and version info for this plugin.
- *packet-foo.c* - Your dissector source.
- *plugin.rc.in* - Contains the DLL resource template for Windows. (optional)

You can find a good example for these files in the gryphon plugin directory. *CMakeLists.txt* has to be modified with the correct plugin name and version info, along with the relevant files to compile. In the main top-level source directory, copy *CMakeListsCustom.txt.example* to *CMakeListsCustom.txt* and add the path of your plugin to the list in `CUSTOM_PLUGIN_SRC_DIR`.

Compile the dissector to a DLL or shared library and either run Wireshark from the build directory as detailed in [Run generated Wireshark](#) or copy the plugin binary into the plugin directory of your Wireshark installation and run that.

**Dissecting the details of the protocol**

Now that we have our basic dissector up and running, let’s do something with it. The simplest thing to do to start with is to just label the payload. This will allow us to set up some of the parts we will need.

The first thing we will do is to build a subtree to decode our results into. This helps to keep things looking nice in the detailed display.

*Example 4. Plugin Packet Dissection.*

```c
static int
dissect_foo(tvbuff_t *tvb, packet_info *pinfo, proto_tree *tree, void *data _U_)
{
    col_set_str(pinfo->cinfo, COL_PROTOCOL, "FOO");
    /* Clear out stuff in the info column */
    col_clear(pinfo->cinfo, COL_INFO);

    proto_item *ti = proto_tree_add_item(tree, proto_foo, tvb, 0, -1, ENC_NA);

    return tvb_captured_length(tvb);
}
```

What we’re doing here is adding a subtree to the dissection. This subtree will hold all the details of
this protocol and so not clutter up the display when not required.

We are also marking the area of data that is being consumed by this protocol. In our case it's all that has been passed to us, as we're assuming this protocol does not encapsulate another. Therefore, we add the new tree node with `proto_tree_add_item()`, adding it to the passed in tree, label it with the protocol, use the passed in tvb buffer as the data, and consume from 0 to the end (-1) of this data. ENC_NA ("not applicable") is specified as the "encoding" parameter.

After this change, there should be a label in the detailed display for the protocol, and selecting this will highlight the remaining contents of the packet.

Now let's go to the next step and add some protocol dissection. For this step we'll need to construct a couple of tables that help with dissection. This needs some additions to the `proto_register_foo()` function shown previously.

Two statically allocated arrays are added at the beginning of `proto_register_foo()`. The arrays are then registered after the call to `proto_register_protocol()`.
Example 5. Registering data structures.

```c
void
proto_register_foo(void)
{
    static hf_register_info hf[] = {
        { &hf_foo_pdu_type,
            { "FOO PDU Type", "foo.type",
                FT_UINT8, BASE_DEC,
                NULL, 0x0,
                NULL, HFILL }
        }
    };

    /* Setup protocol subtree array */
    static gint *ett[] = {
        &ett_foo
    };

    proto_foo = proto_register_protocol (
        "FOO Protocol", /* name       */
        "FOO",      /* short name */
        "foo"       /* abbrev     */
    );

    proto_register_field_array(proto_foo, hf, array_length(hf));
    proto_register_subtree_array(ett, array_length(ett));
}
```

The variables `hf_foo_pdu_type` and `ett_foo` also need to be declared somewhere near the top of the file.

Example 6. Dissector data structure globals.

```c
static int hf_foo_pdu_type = -1;
static gint ett_foo = -1;
```

Now we can enhance the protocol display with some detail.
Example 7. Dissector starting to dissect the packets.

```c
proto_item *ti = proto_tree_add_item(tree, proto_foo, tvb, 0, -1, ENC_NA);
proto_tree *foo_tree = proto_item_add_subtree(ti, ett_foo);
proto_tree_add_item(foo_tree, hf_foo_pdu_type, tvb, 0, 1, ENC_BIG_ENDIAN);
```

Now the dissection is starting to look more interesting. We have picked apart our first bit of the protocol. One byte of data at the start of the packet that defines the packet type for foo protocol.

The `proto_item_add_subtree()` call has added a child node to the protocol tree which is where we will do our detail dissection. The expansion of this node is controlled by the `ett_foo` variable. This remembers if the node should be expanded or not as you move between packets. All subsequent dissection will be added to this tree, as you can see from the next call. A call to `proto_tree_add_item()` in the `foo_tree`, this time using the `hf_foo_pdu_type` to control the formatting of the item. The pdu type is one byte of data, starting at 0. We assume it is in network order (also called big endian), so that is why we use `ENC_BIG_ENDIAN`. For a 1-byte quantity, there is no order issue, but it is good practice to make this the same as any multibyte fields that may be present, and as we will see in the next section, this particular protocol uses network order.

If we look in detail at the `hf_foo_pdu_type` declaration in the static array we can see the details of the definition.

- `hf_foo_pdu_type` - The index for this node.
- `FOO PDU Type` - The label for this item.
- `foo.type` - This is the filter string. It enables us to type constructs such as `foo.type=1` into the filter box.
- `FT_UINT8` - This specifies this item is an 8bit unsigned integer. This tallies with our call above where we tell it to only look at one byte.
- `BASE_DEC` - For an integer type, this tells it to be printed as a decimal number. It could be hexadecimal (BASE_HEX) or octal (BASE_OCT) if that made more sense.

We'll ignore the rest of the structure for now.

If you install this plugin and try it out, you'll see something that begins to look useful.

Now let's finish off dissecting the simple protocol. We need to add a few more variables to the `hfarray`, and a couple more procedure calls.

Example 8. Wrapping up the packet dissection.

```c
... static int hf_foo_flags = -1;
static int hf_foo_sequenceno = -1;
```
static int hf_foo_initialip = -1;
...

static int
dissect_foo(tvbuff_t *tvb, packet_info *pinfo, proto_tree *tree, void *data _U_)
{
    gint offset = 0;
    ...
    proto_item *ti = proto_tree_add_item(tree, proto_foo, tvb, 0, -1, ENC_NA);
    proto_tree *foo_tree = proto_item_add_subtree(ti, ett_foo);
    proto_tree_add_item(foo_tree, hf_foo_pdu_type, tvb, offset, 1, ENC_BIG_ENDIAN);
    offset += 1;
    proto_tree_add_item(foo_tree, hf_foo_flags, tvb, offset, 1, ENC_BIG_ENDIAN);
    offset += 1;
    proto_tree_add_item(foo_tree, hf_foo_sequenceno, tvb, offset, 2,
        ENC_BIG_ENDIAN);
    offset += 2;
    proto_tree_add_item(foo_tree, hf_foo_initialip, tvb, offset, 4,
        ENC_BIG_ENDIAN);
    offset += 4;
    ...
    return tvb_captured_length(tvb);
}

void
proto_register_foo(void) {
    ...
    ...
    { &hf_foo_flags,
        { "FOO PDU Flags", "foo.flags",
            FT_UINT8, BASE_HEX,
            NULL, 0x0,
            NULL, HFILL } 
    },
    { &hf_foo_sequenceno,
        { "FOO PDU Sequence Number", "foo.seqn",
            FT_UINT16, BASE_DEC,
            NULL, 0x0,
            NULL, HFILL } 
    },
    { &hf_foo_initialip,
        { "FOO PDU Initial IP", "foo.initialip",
            FT_IPV4, BASE_NONE,
            NULL, 0x0,
            NULL, HFILL } 
    },
This dissects all the bits of this simple hypothetical protocol. We’ve introduced a new variable offset into the mix to help keep track of where we are in the packet dissection. With these extra bits in place, the whole protocol is now dissected.

**Improving the dissection information**

We can certainly improve the display of the protocol with a bit of extra data. The first step is to add some text labels. Let’s start by labeling the packet types. There is some useful support for this sort of thing by adding a couple of extra things. First we add a simple table of type to name.

*Example 9. Naming the packet types.*

```c
static const value_string packettypenames[] = {
    { 1, "Initialise" },
    { 2, "Terminate" },
    { 3, "Data" },
    { 0, NULL }
};
```

This is a handy data structure that can be used to look up a name for a value. There are routines to directly access this lookup table, but we don’t need to do that, as the support code already has that added in. We just have to give these details to the appropriate part of the data, using the `VALS` macro.

*Example 10. Adding Names to the protocol.*

```c
{ &hf_foo_pdu_type,
    { "FOO PDU Type", "foo.type",
      FT_UINT8, BASE_DEC,
      VALS(packettypenames), 0x0,
      NULL, HFILL }
}
```

This helps in deciphering the packets, and we can do a similar thing for the flags structure. For this we need to add some more data to the table though.
Example 11. Adding Flags to the protocol.

```c
#define FOO_START_FLAG   0x01
#define FOO_END_FLAG     0x02
#define FOO_PRIORITY_FLAG 0x04

static int hf_foo_startflag = -1;
static int hf_foo_endflag = -1;
static int hf_foo_priorityflag = -1;

static int dissect_foo(tvbuff_t *tvb, packet_info *pinfo, proto_tree *tree, void *data _U_)
{
    ... static const int* bits[] = {
        &hf_foo_startflag,
        &hf_foo_endflag,
        &hf_foo_priorityflag
    };

    proto_tree_add_bitmask(foo_tree, tvb, offset, hf_foo_flags, ett_foo, bits, ENC_BIG_ENDIAN);
    offset += 1;
    ...
    ... return tvb_captured_length(tvb);
}

void proto_register_foo(void) {
    ...
    ...
    { &hf_foo_startflag,
        { "FOO PDU Start Flags", "foo.flags.start",
        FT_BOOLEAN, 8,
        NULL, FOO_START_FLAG,
        NULL, HFILL } },
    { &hf_foo_endflag,
        { "FOO PDU End Flags", "foo.flags.end",
        FT_BOOLEAN, 8,
        NULL, FOO_END_FLAG,
        NULL, HFILL } },
    { &hf_foo_priorityflag,
        { "FOO PDU Priority Flags", "foo.flags.priority",
        FT_BOOLEAN, 8,
        NULL, FOO_PRIORITY_FLAG,
        NULL, HFILL } }
}
```
Some things to note here. For the flags, as each bit is a different flag, we use the type `FT_BOOLEAN`, as the flag is either on or off. Second, we include the flag mask in the 7th field of the data, which allows the system to mask the relevant bit. We've also changed the 5th field to 8, to indicate that we are looking at an 8 bit quantity when the flags are extracted. Then finally we add the extra constructs to the dissection routine.

This is starting to look fairly full featured now, but there are a couple of other things we can do to make things look even more pretty. At the moment our dissection shows the packets as "Foo Protocol" which whilst correct is a little uninformative. We can enhance this by adding a little more detail. First, let's get hold of the actual value of the protocol type. We can use the handy function `tvb_get_guint8()` to do this. With this value in hand, there are a couple of things we can do. First we can set the INFO column of the non-detailed view to show what sort of PDU it is - which is extremely helpful when looking at protocol traces. Second, we can also display this information in the dissection window.
So here, after grabbing the value of the first 8 bits, we use it with one of the built-in utility routines \texttt{val_to_str()}, to lookup the value. If the value isn’t found we provide a fallback which just prints the value in hex. We use this twice, once in the INFO field of the columns— if it’s displayed, and similarly we append this data to the base of our dissecting tree.

### How to handle transformed data

Some protocols do clever things with data. They might possibly encrypt the data, or compress data, or part of it. If you know how these steps are taken it is possible to reverse them within the dissector.

As encryption can be tricky, let’s consider the case of compression. These techniques can also work for other transformations of data, where some step is required before the data can be examined.

What basically needs to happen here, is to identify the data that needs conversion, take that data and transform it into a new stream, and then call a dissector on it. Often this needs to be done "on-the-fly" based on clues in the packet. Sometimes this needs to be used in conjunction with other techniques, such as packet reassembly. The following shows a technique to achieve this effect.
The first steps here are to recognise the compression. In this case a flag byte alerts us to the fact the remainder of the packet is compressed. Next we retrieve the original size of the packet, which in this case is conveniently within the protocol. If it’s not, it may be part of the compression routine to work it out for you, in which case the logic would be different.

So armed with the size, a buffer is allocated to receive the uncompressed data using `wmem_alloc()` in `pinfo`→`pool` memory, and the packet is decompressed into it. The `tvb_get_ptr()` function is useful to get a pointer to the raw data of the packet from the offset onwards. In this case the decompression routine also needs to know the length, which is given by the `tvb_captured_length_remaining()` function.

Next we build a new tvb buffer from this data, using the `tvb_new_child_real_data()` call. This data is a child of our original data, so calling this function also acknowledges that. No need to call `tvb_set_free_cb()` as the `pinfo`→`pool` was used (the memory block will be automatically freed when the `pinfo` pool lifetime expires). Finally we add this tvb as a new data source, so that the detailed display can show the decompressed bytes as well as the original.

After this has been set up the remainder of the dissector can dissect the buffer `next_tvb`, as it’s a new buffer the offset needs to be 0 as we start again from the beginning of this buffer. To make the rest of the dissector work regardless of whether compression was involved or not, in the case that compression was not signaled, we use `tvb_new_subset_remaining()` to deliver us a new buffer based on the old one but starting at the current offset, and extending to the end. This makes dissecting the packet from this point on exactly the same regardless of compression.
How to reassemble split packets

Some protocols have times when they have to split a large packet across multiple other packets. In this case the dissection can't be carried out correctly until you have all the data. The first packet doesn't have enough data, and the subsequent packets don't have the expect format. To dissect these packets you need to wait until all the parts have arrived and then start the dissection.

The following sections will guide you through two common cases. For a description of all possible functions, structures and parameters, see epan/reassemble.h.

How to reassemble split UDP packets

As an example, let's examine a protocol that is layered on top of UDP that splits up its own data stream. If a packet is bigger than some given size, it will be split into chunks, and somehow signaled within its protocol.

To deal with such streams, we need several things to trigger from. We need to know that this packet is part of a multi-packet sequence. We need to know how many packets are in the sequence. We also need to know when we have all the packets.

For this example we'll assume there is a simple in-protocol signaling mechanism to give details. A flag byte that signals the presence of a multi-packet sequence and also the last packet, followed by an ID of the sequence and a packet sequence number.

```
msg_pkt ::= SEQUENCE {
   ....
   flags ::= SEQUENCE {
      fragment BOOLEAN,
      last_fragment BOOLEAN,
   }
   msg_id INTEGER(0..65535),
   frag_id INTEGER(0..65535),
   ....
}
```
# Example 14. Reassembling fragments - Part 1

```c
#include <epan/reassemble.h>
...
save_fragmented = pinfo->fragmented;
flags = tvb_get_guint8(tvb, offset); offset++;
if (flags & FL_FRAGMENT) /* fragmented */
    tvbuff_t* new tvb = NULL;
    fragment_data *frag_msg = NULL;
guint16 msg_seqid = tvb_get_ntohs(tvb, offset); offset += 2;
guint16 msg_num = tvb_get_ntohs(tvb, offset); offset += 2;

    pinfo->fragmented = TRUE;
    frag_msg = fragment_add_seq_check(msg_reassembly_table,
        tvb, offset, pinfo,
        msg_seqid, NULL, /* ID for fragments belonging together */
        msg_num, /* fragment sequence number */
        tvb_captured_length_remaining(tvb, offset), /* fragment length - to the
        end */
        flags & FL_FRAG_LAST); /* More fragments? */
```

We start by saving the fragmented state of this packet, so we can restore it later. Next comes some protocol specific stuff, to dig the fragment data out of the stream if it's present. Having decided it is present, we let the function `fragment_add_seq_check()` do its work. We need to provide this with a certain amount of parameters:

- The `msg_reassembly_table` table is for bookkeeping and is described later.
- The tvb buffer we are dissecting.
- The offset where the partial packet starts.
- The provided packet info.
- The sequence number of the fragment stream. There may be several streams of fragments in flight, and this is used to key the relevant one to be used for reassembly.
- Optional additional data for identifying the fragment. Can be set to `NULL` (as is done in the example) for most dissectors.
- `msg_num` is the packet number within the sequence.
- The length here is specified as the rest of the tvb as we want the rest of the packet data.
- Finally a parameter that signals if this is the last fragment or not. This might be a flag as in this case, or there may be a counter in the protocol.
Having passed the fragment data to the reassembly handler, we can now check if we have the whole message. If there is enough information, this routine will return the newly reassembled data buffer.

After that, we add a couple of informative messages to the display to show that this is part of a sequence. Then a bit of manipulation of the buffers and the dissection can proceed. Normally you will probably not bother dissecting further unless the fragments have been reassembled as there won't be much to find. Sometimes the first packet in the sequence can be partially decoded though if you wish.

Now the mysterious data we passed into the `fragment_add_seq_check()`.
Example 16. Reassembling fragments - Initialisation

```c
static reassembly_table reassembly_table;

static void
proto_register_msg(void)
{
    reassembly_table_register(&msg_reassemble_table,
                             &addresses_ports_reassembly_table_functions);
}
```

First a `reassembly_table` structure is declared and initialised in the protocol initialisation routine. The second parameter specifies the functions that should be used for identifying fragments. We will use `addresses_ports_reassembly_table_functions` in order to identify fragments by the given sequence number (`msg_seqid`), the source and destination addresses and ports from the packet.

Following that, a `fragment_items` structure is allocated and filled in with a series of ett items, hf data items, and a string tag. The ett and hf values should be included in the relevant tables like all the other variables your protocol may use. The hf variables need to be placed in the structure something like the following. Of course the names may need to be adjusted.

Example 17. Reassembling fragments - Data

```c
...
static int hf_msg_fragments = -1;
static int hf_msg_fragment = -1;
static int hf_msg_fragment_overlap = -1;
static int hf_msg_fragment_overlap_conflicts = -1;
static int hf_msg_fragment_multiple_tails = -1;
static int hf_msg_fragment_too_long_fragment = -1;
static int hf_msg_fragment_error = -1;
static int hf_msg_fragment_count = -1;
static int hf_msg_reassembled_in = -1;
static int hf_msg_reassembled_length = -1;
...
static gint ett_msg_fragment = -1;
static gint ett_msg_fragments = -1;
...
static const fragment_items msg_frag_items = {
    /* Fragment subtrees */
    &ett_msg_fragment,
    &ett_msg_fragments,
    /* Fragment fields */
    &hf_msg_fragments,
```
static hf_register_info hf[] = 
{
    ...
    {&hf_msg_fragments,
        {"Message fragments", "msg.fragments",
            FT_NONE, BASE_NONE, NULL, 0x00, NULL, HFILL } },
    {&hf_msg_fragment,
        {"Message fragment", "msg.fragment",
            FT_FRAMENUM, BASE_NONE, NULL, 0x00, NULL, HFILL } },
    {&hf_msg_fragment_overlap,
        {"Message fragment overlap", "msg.fragment.overlap",
            FT_BOOLEAN, 0, NULL, 0x00, NULL, HFILL } },
    {&hf_msg_fragment_overlap_conflicts,
        {"Message fragment overlapping with conflicting data",
            "msg.fragment.overlap.conflicts",
            FT_BOOLEAN, 0, NULL, 0x00, NULL, HFILL } },
    {&hf_msg_fragment_multiple_tails,
        {"Message has multiple tail fragments",
            "msg.fragment.multiple_tails",
            FT_BOOLEAN, 0, NULL, 0x00, NULL, HFILL } },
    {&hf_msg_fragment_too_long_fragment,
        {"Message fragment too long", "msg.fragment.too_long_fragment",
            FT_BOOLEAN, 0, NULL, 0x00, NULL, HFILL } },
    {&hf_msg_fragment_error,
        {"Message defragmentation error", "msg.fragment.error",
            FT_FRAMENUM, BASE_NONE, NULL, 0x00, NULL, HFILL } },
    {&hf_msg_fragment_count,
        {"Message fragment count", "msg.fragment.count",
            FT_UINT32, BASE_DEC, NULL, 0x00, NULL, HFILL } },
    {&hf_msg_reassembled_in,
        {"Reassembled in", "msg.reassembled.in",
            FT_FRAMENUM, BASE_NONE, NULL, 0x00, NULL, HFILL } },
    {&hf_msg_reassembled_length,
        {"Reassembled length field", "msg.reassembled.length",
            FT_UINT32, BASE_DEC, NULL, 0x00, NULL, HFILL } },
};
These hf variables are used internally within the reassembly routines to make useful links, and to add data to the dissection. It produces links from one packet to another, such as a partial packet having a link to the fully reassembled packet. Likewise there are back pointers to the individual packets from the reassembled one. The other variables are used for flagging up errors.

**How to reassemble split TCP Packets**

A dissector gets a `tvbuff_t` pointer which holds the payload of a TCP packet. This payload contains the header and data of your application layer protocol.

When dissecting an application layer protocol you cannot assume that each TCP packet contains exactly one application layer message. One application layer message can be split into several TCP packets.

You also cannot assume that a TCP packet contains only one application layer message and that the message header is at the start of your TCP payload. More than one messages can be transmitted in one TCP packet, so that a message can start at an arbitrary position.

This sounds complicated, but there is a simple solution. `tcp_dissect_pdus()` does all this tcp packet reassembling for you. This function is implemented in `epan/dissectors/packet-tcp.h`. 
As you can see this is really simple. Just call `tcp_dissect_pdus()` in your main dissection routine and move your message parsing code into another function. This function gets called whenever a message has been reassembled.
The parameters tvb, pinfo, tree and data are just handed over to \texttt{tcp_dissect_pdus()}. The 4th parameter is a flag to indicate if the data should be reassembled or not. This could be set according to a dissector preference as well. Parameter 5 indicates how much data has at least to be available to be able to determine the length of the foo message. Parameter 6 is a function pointer to a method that returns this length. It gets called when at least the number of bytes given in the previous parameter is available. Parameter 7 is a function pointer to your real message dissector. Parameter 8 is the data passed in from parent dissector.

Protocols which need more data before the message length can be determined can return zero. Other values smaller than the fixed length will result in an exception.

**How to tap protocols**

Adding a Tap interface to a protocol allows it to do some useful things. In particular you can produce protocol statistics from the tap interface.

A tap is basically a way of allowing other items to see what’s happening as a protocol is dissected. A tap is registered with the main program, and then called on each dissection. Some arbitrary protocol specific data is provided with the routine that can be used.

To create a tap, you first need to register a tap. A tap is registered with an integer handle, and registered with the routine \texttt{register_tap()}. This takes a string name with which to find it again.

**Example 19. Initialising a tap**

```c
#include <epan/packet.h>
#include <epan/tap.h>

static int foo_tap = -1;

struct FooTap {
    gint packet_type;
    gint priority;
    ...
};

void proto_register_foo(void)
{
    ...
    foo_tap = register_tap("foo");
}
```

Whilst you can program a tap without protocol specific data, it is generally not very useful. Therefore it’s a good idea to declare a structure that can be passed through the tap. This needs to be a static structure as it will be used after the dissection routine has returned. It’s generally best to
pick out some generic parts of the protocol you are dissecting into the tap data. A packet type, a priority or a status code maybe. The structure really needs to be included in a header file so that it can be included by other components that want to listen in to the tap.

Once you have these defined, it’s simply a case of populating the protocol specific structure and then calling `tap_queue_packet`, probably as the last part of the dissector.

Example 20. Calling a protocol tap

```c
static int dissect_foo(tvbuff_t *tvb, packet_info *pinfo, proto_tree *tree, void *data _U_)
{
    ...
    fooinfo = wmem_alloc(wmem_packet_scope(), sizeof(struct FooTap));
    fooinfo->packet_type = tvb_get_guint8(tvb, 0);
    fooinfo->priority = tvb_get_ntohs(tvb, 8);
    ...
    tap_queue_packet(foo_tap, pinfo, fooinfo);

    return tvb_captured_length(tvb);
}
```

This now enables those interested parties to listen in on the details of this protocol conversation.

How to produce protocol stats

Given that you have a tap interface for the protocol, you can use this to produce some interesting statistics (well presumably interesting!) from protocol traces.

This can be done in a separate plugin, or in the same plugin that is doing the dissection. The latter scheme is better, as the tap and stats module typically rely on sharing protocol specific data, which might get out of step between two different plugins.

Here is a mechanism to produce statistics from the above TAP interface.
/* register all http trees */
static void register_foo_stat_trees(void) {
    stats_tree_register_plugin("foo", "foo", "Foo/Packet Types", 0,
        foo_stats_tree_packet, foo_stats_tree_init, NULL);
}

WS_DLL_PUBLIC_DEF void plugin_register_tap_listener(void)
{
    register_foo_stat_trees();
}

Working from the bottom up, first the plugin interface entry point is defined, plugin_register_tap_listener(). This simply calls the initialisation function register_foo_stat_trees().

This in turn calls the stats_tree_register_plugin() function, which takes three strings, an integer, and three callback functions.

1. This is the tap name that is registered.
2. An abbreviation of the stats name.
3. The name of the stats module. A “/” character can be used to make sub menus.
4. Flags for per-packet callback
5. The function that will called to generate the stats.
6. A function that can be called to initialise the stats data.
7. A function that will be called to clean up the stats data.

In this case we only need the first two functions, as there is nothing specific to clean up.
Example 22. Initialising a stats session

```c
static const guint8* st_str_packets = "Total Packets";
static const guint8* st_str_packet_types = "FOO Packet Types";
static int st_node_packets = -1;
static int st_node_packet_types = -1;

static void foo_stats_tree_init(stats_tree* st)
{
    st_node_packets = stats_tree_create_node(st, st_str_packets, 0, TRUE);
    st_node_packet_types = stats_tree_create_pivot(st, st_str_packet_types,
                                                   st_node_packets);
}
```

In this case we create a new tree node, to handle the total packets, and as a child of that we create a pivot table to handle the stats about different packet types.

Example 23. Generating the stats

```c
static int foo_stats_tree_packet(stats_tree* st, packet_info* pinfo,
                                  epan_dissect_t* edt, const void* p)
{
    struct FooTap *pi = (struct FooTap *)p;
    tick_stat_node(st, st_str_packets, 0, FALSE);
    stats_tree_tick_pivot(st, st_node_packet_types,
                           val_to_str(pi->packet_type, msgtypevalues, "Unknown packet type (%d)"));
    return 1;
}
```

In this case the processing of the stats is quite simple. First we call the `tick_stat_node` for the `st_str_packets` packet node, to count packets. Then a call to `stats_tree_tick_pivot()` on the `st_node_packet_types` subtree allows us to record statistics by packet type.

How to use conversations

Some info about how to use conversations in a dissector can be found in the file `doc/README.dissector`, chapter 2.2.
idl2wrs: Creating dissectors from CORBA IDL files

Many of Wireshark’s dissectors are automatically generated. This section shows how to generate one from a CORBA IDL file.

What is it?

As you have probably guessed from the name, idl2wrs takes a user specified IDL file and attempts to build a dissector that can decode the IDL traffic over GIOP. The resulting file is “C” code, that should compile okay as a Wireshark dissector.

idl2wrs parses the data struct given to it by the omniidl compiler, and using the GIOP API available in packet-giop.[ch], generates get_CDR_xxx calls to decode the CORBA traffic on the wire.

It consists of 4 main files.

README.idl2wrs
   This document

wireshark_be.py
   The main compiler backend

wireshark_gen.py
   A helper class, that generates the C code.

idl2wrs
   A simple shell script wrapper that the end user should use to generate the dissector from the IDL file(s).

Why do this?

It is important to understand what CORBA traffic looks like over GIOP/IIOP, and to help build a tool that can assist in troubleshooting CORBA interworking. This was especially the case after seeing a lot of discussions about how particular IDL types are represented inside an octet stream.

I have also had comments/feedback that this tool would be good for say a CORBA class when teaching students what CORBA traffic looks like “on the wire”.

It is also COOL to work on a great Open Source project such as the case with “Wireshark” (https://www.wireshark.org/).

How to use idl2wrs

To use the idl2wrs to generate Wireshark dissectors, you need the following:

- Python must be installed. See https://python.org/
• `omniidl` from the omniORB package must be available. See [http://omniorb.sourceforge.net/](http://omniorb.sourceforge.net/)

• Of course you need Wireshark installed to compile the code and tweak it if required. idl2wrs is part of the standard Wireshark distribution

To use idl2wrs to generate an Wireshark dissector from an idl file use the following procedure:

• To write the C code to stdout.

  ```
  $ idl2wrs <your_file.idl>
  ```

  e.g.:

  ```
  $ idl2wrs echo.idl
  ```

• To write to a file, just redirect the output.

  ```
  $ idl2wrs echo.idl > packet-test-idl.c
  ```

You may wish to comment out the `register_giop_user_module()` code and that will leave you with heuristic dissection.

If you don't want to use the shell script wrapper, then try steps 3 or 4 instead.

• To write the C code to stdout.

  ```
  $ omniidl -p ./ -b wireshark_be <your file.idl>
  ```

  e.g.:

  ```
  $ omniidl -p ./ -b wireshark_be echo.idl
  ```

• To write to a file, just redirect the output.

  ```
  $ omniidl -p ./ -b wireshark_be echo.idl > packet-test-idl.c
  ```

You may wish to comment out the `register_giop_user_module()` code and that will leave you with heuristic dissection.

• Copy the resulting C code to subdirectory epan/dissectors/ inside your Wireshark source directory.
$ cp packet-test-idl.c /dir/where/wireshark/lives/epan/dissectors/

The new dissector has to be added to CMakeLists.txt in the same directory. Look for the declaration DISSECTOR_SRC and add the new dissector there. For example,

```
DISSECTOR_SRC = \\
  ${CMAKE_CURRENT_SOURCE_DIR}/packet-2dparityfec.c \\
  ${CMAKE_CURRENT_SOURCE_DIR}/packet-3com-njack.c \\
  ...
```

becomes

```
DISSECTOR_SRC = \\
  ${CMAKE_CURRENT_SOURCE_DIR}/packet-test-idl.c \ 
  ${CMAKE_CURRENT_SOURCE_DIR}/packet-2dparityfec.c \ 
  ${CMAKE_CURRENT_SOURCE_DIR}/packet-3com-njack.c \ 
  ...
```

For the next steps, go up to the top of your Wireshark source directory.

- Create a build dir

  ```bash
  $ mkdir build && cd build
  ```

- Run cmake

  ```bash
  $ cmake ..
  ```

- Build the code

  ```bash
  $ make
  ```

- Good Luck!!

**TODO**

- Exception code not generated (yet), but can be added manually.
- Enums not converted to symbolic values (yet), but can be added manually.
- Add command line options etc
• More I am sure :-)

Limitations

See the TODO list inside packet-giop.c

Notes

The `-p ./` option passed to omniidl indicates that the wireshark_be.py and wireshark_gen.py are residing in the current directory. This may need tweaking if you place these files somewhere else.

If it complains about being unable to find some modules (e.g. tempfile.py), you may want to check if PYTHONPATH is set correctly.
Lua Support in Wireshark

Introduction

Lua is a powerful light-weight programming language designed for extending applications. Wireshark contains an embedded Lua 5.2 interpreter which can be used to write dissectors, taps, and capture file readers and writers.

Wireshark's Lua interpreter starts by loading a file named init.lua from Wireshark's global configuration directory. The global configuration directory's init.lua controls whether or not Lua scripts are enabled via the enable_lua variable. Lua scripts are enabled by default. To disable Lua scripts, set the enable_lua variable to false. Wireshark 2.6 and earlier enabled or disabled Lua scripts using the variable disable_lua (deprecated). If both enable_lua and disable_lua are present, disable_lua is ignored.

If Lua is enabled, Wireshark will try to load a file named init.lua from the user's personal configuration directory and all files ending with .lua in the global and the personal plugins directory.

The command line option -X lua_script:file.lua can also be used to load specific Lua scripts.

The Lua code is executed after all protocol dissectors are initialized and before reading any file.

Wireshark for Windows uses a modified Lua runtime (lua-unicode) to support Unicode (UTF-8) filesystem paths. This brings consistency with other platforms (for example, Linux and macOS).

Example: Creating a Menu with Lua

The code below adds a menu "Lua Dialog Test" under the Tools menu. When selected, it opens a dialog prompting the user for input and then opens a text window with the output.
-- Define the menu entry's callback
local function dialog_menu()
    local function dialog_func(person, eyes, hair)
        local window = TextWindow.new("Person Info");
        local message = string.format("Person %s with %s eyes and %s hair.", person, eyes, hair);
        window:set(message);
    end

    new_dialog("Dialog Test", dialog_func, "A Person", "Eyes", "Hair")
end

-- Create the menu entry
register_menu("Lua Dialog Test", dialog_menu, MENU_TOOLS_UNSORTED)

-- Notify the user that the menu was created
if gui_enabled() then
    local splash = TextWindow.new("Hello!");
    splash:set("Wireshark has been enhanced with a useless feature.
    
    Go to 'Tools->Lua Dialog Test' and check it out!")
end

Example: Dissector written in Lua

local p_multi = Proto("multi", "MultiProto");

local vs_protos = {
    [2] = "mtp2",
    [3] = "mtp3",
    [5] = "h248",
    [6] = "ranap",
    [7] = "rnsap",
    [8] = "nbap"
}

local f_proto = ProtoField.uint8("multi.protocol", "Protocol", base.DEC, vs_protos)
local f_dir = ProtoField.uint8("multi.direction", "Direction", base.DEC, { [1] = "incoming", [0] = "outgoing"})
local f_text = ProtoField.string("multi.text", "Text")

p_multi.fields = { f_proto, f_dir, f_text }

local data_dis = Dissector.get("data")
local protos = {
    [2] = Dissector.get("mtp2"),
    [3] = Dissector.get("mtp3"),

wtap_encap_table:add(wtap.USER15, p_multi)
wtap_encap_table:add(wtap.USER12, p_multi)
udp_encap_table:add(7555, p_multi)
Example: Listener written in Lua

```lua
-- This program will register a menu that will open a window with a count of occurrences
-- of every address in the capture

local function menuable_tap()

    -- Declare the window we will use
    local tw = TextWindow.new("Address Counter")

    -- This will contain a hash of counters of appearances of a certain address
    local ips = {}

    -- this is our tap
    local tap = Listener.new();

    local function remove()
        -- this way we remove the listener that otherwise will remain running
        -- indefinitely
        tap:remove();
    end

    -- we tell the window to call the remove() function when closed
    tw:set_atclose(remove)

-- this function will be called once for each packet
function tap.packet(pinfo, tvb)
    local src = ips[tostring(pinfo.src)] or 0
    local dst = ips[tostring(pinfo.dst)] or 0

    ips[tostring(pinfo.src)] = src + 1
    ips[tostring(pinfo.dst)] = dst + 1
end

-- this function will be called once every few seconds to update our window
function tap.draw(t)
    tw:clear()
    for ip, num in pairs(ips) do
        tw:append(ip .. "\t" .. num .. "\n");
    end
end

-- this function will be called whenever a reset is needed
-- e.g. when reloading the capture file
function tap.reset()
    tw:clear()
    ips = {}
end
```
end

-- Ensure that all existing packets are processed.
retap_packets()
end

-- using this function we register our function
-- to be called when the user selects the Tools->Test->Packets menu
register_menu("Test/Packets", menuable_tap, MENU_TOOLS_UNSORTED)
Wireshark’s Lua API Reference Manual

This Part of the User Guide describes the Wireshark specific functions in the embedded Lua.

Classes group certain functionality, the following notational conventions are used:

- `Class:MethodName()` represents a class method (named `MethodName`) on class `Class`, taking no arguments.
- `Class:MethodName(a)` represents a class method taking one argument.
- `Class:MethodName(…)` represents a class method taking a variable number of arguments.
- `Class:MethodName()` represents an instance method (named `MethodName`) on an instance of class `Class`, taking no arguments. Note the lowercase notation in the documentation to clarify an instance.
- `Class:prop` represents a property `prop` on the instance of class `Class`.

Trying to access a non-existing property, function or method currently gives an error, but do not rely on it as the behavior may change in the future.

Saving capture files

The classes/functions defined in this module are for using a `Dumper` object to make Wireshark save a capture file to disk. `Dumper` represents Wireshark's built-in file format writers (see the `wtap_filetypes` table in `init.lua`).

To have a Lua script create its own file format writer, see the chapter titled "Custom file format reading/writing".

Dumper

`Dumper.new(filename, [filetype], [encap])`

Creates a file to write packets. `Dumper:new_for_current()` will probably be a better choice.

Arguments

filename

The name of the capture file to be created.

filetype (optional)

The type of the file to be created - a number entry from the `wtap_filetypes` table in `init.lua`.

encap (optional)

The encapsulation to be used in the file to be created - a number entry from the `wtap_encaps` table in `init.lua`.

Returns

The newly created Dumper object

dumper:close()
Closes a dumper.

Errors

• Cannot operate on a closed dumper

dumper:flush()
Writes all unsaved data of a dumper to the disk.

dumper:dump(timestamp, pseudoheader, bytearray)
Dumps an arbitrary packet. Note: Dumper:dump_current() will fit best in most cases.

Arguments

timestamp
  The absolute timestamp the packet will have.

pseudoheader
  The PseudoHeader to use.

bytearray
  The data to be saved

dumper:new_for_current([filetype])
Creates a capture file using the same encapsulation as the one of the current packet.

Arguments

filetype (optional)
  The file type. Defaults to pcap.

Returns

The newly created Dumper Object

Errors

• Cannot be used outside a tap or a dissector
dumper:dump_current()

Dumps the current packet as it is.

Errors

- Cannot be used outside a tap or a dissector

PseudoHeader

A pseudoheader to be used to save captured frames.

PseudoHeader.none()

Creates a "no" pseudoheader.

Returns

A null pseudoheader

PseudoHeader.eth([fcslen])

Creates an ethernet pseudoheader.

Arguments

fcslen (optional)

The fcs length

Returns

The ethernet pseudoheader

PseudoHeader.atm([aal], [vpi], [vci], [channel], [cells], [aal5u2u], [aal5len])

Creates an ATM pseudoheader.

Arguments

aal (optional)

AAL number

vpi (optional)

VPI

cvi (optional)

VCI
channel (optional)
Channel

cells (optional)
Number of cells in the PDU

aal5u2u (optional)
AAL5 User to User indicator

aal5len (optional)
AAL5 Len

Returns
The ATM pseudoheader

PseudoHeader.mtp2([sent], [annexa], [linknum])
Creates an MTP2 PseudoHeader.

Arguments

sent (optional)
True if the packet is sent, False if received.

annexa (optional)
True if annex A is used.

linknum (optional)
Link Number.

Returns
The MTP2 pseudoheader

Obtaining dissection data

Field
A Field extractor to to obtain field values. A Field object can only be created outside of the callback functions of dissectors, post-dissectors, heuristic-dissectors, and taps.

Once created, it is used inside the callback functions, to generate a FieldInfo object.
Field.new(fieldname)
Create a Field extractor.

Arguments

fieldname
The filter name of the field (e.g. ip.addr)

Returns

The field extractor

Errors

• A Field extractor must be defined before Taps or Dissectors get called

Field.list()

Gets a Lua array table of all registered field filter names.

NOTE  This is an expensive operation, and should only be used for troubleshooting.

Since: 1.11.3

Returns

The array table of field filter names

field:__call()

Obtain all values (see FieldInfo) for this field.

Returns

All the values of this field

Errors

• Fields cannot be used outside dissectors or taps

field:__tostring()

Obtain a string with the field filter name.

field.name

Mode: Retrieve only.
The filter name of this field, or nil.
Since: 1.99.8

field.display
Mode: Retrieve only.
The full display name of this field, or nil.
Since: 1.99.8

field.type
Mode: Retrieve only.
The ftype of this field, or nil.
Since: 1.99.8

FieldInfo
An extracted Field from dissected packet data. A FieldInfo object can only be used within the
callback functions of dissectors, post-dissectors, heuristic-dissectors, and taps.

A FieldInfo can be called on either existing Wireshark fields by using either Field.new() or Field()
before-hand, or it can be called on new fields created by Lua from a ProtoField.

fieldinfo:__len()
Obtain the Length of the field

fieldinfo:__unm()
Obtain the Offset of the field

fieldinfo:__call()
Obtain the Value of the field.

Previous to 1.11.4, this function retrieved the value for most field types, but for ftypes.UINT_BYTES it
retrieved the ByteArray of the field's entire TvbRange. In other words, it returned a ByteArray that
included the leading length byte(s), instead of just the value bytes. That was a bug, and has been
changed in 1.11.4. Furthermore, it retrieved an ftypes.GUID as a ByteArray, which is also incorrect.

If you wish to still get a ByteArray of the TvbRange, use FieldInfo:get_range() to get the TvbRange, and
then use Tvb:bytes() to convert it to a ByteArray.
fieldinfo: __tostring()
The string representation of the field.

fieldinfo: __eq()
Checks whether lhs is within rhs.

fieldinfo: __le()
Checks whether the end byte of lhs is before the end of rhs.

Errors
• Data source must be the same for both fields

fieldinfo: __lt()
Checks whether the end byte of rhs is before the beginning of rhs.

Errors
• Data source must be the same for both fields

fieldinfo.len
Mode: Retrieve only.
The length of this field.

fieldinfo.offset
Mode: Retrieve only.
The offset of this field.

fieldinfo.value
Mode: Retrieve only.
The value of this field.

fieldinfo.label
Mode: Retrieve only.
The string representing this field.
**fieldinfo.display**

Mode: Retrieve only.

The string display of this field as seen in GUI.

**fieldinfo.type**

Mode: Retrieve only.

The internal field type, a number which matches one of the ftype values in `init.lua`.

Since: 1.99.8

**fieldinfo.source**

Mode: Retrieve only.

The source `Tvb` object the `FieldInfo` is derived from, or nil if there is none.

Since: 1.99.8

**fieldinfo.range**

Mode: Retrieve only.

The `TvbRange` covering the bytes of this field in a `Tvb`.

**fieldinfo.generated**

Mode: Retrieve only.

Whether this field was marked as generated (boolean).

**fieldinfo.hidden**

Mode: Retrieve only.

Whether this field was marked as hidden (boolean).

Since: 1.99.8

**fieldinfo.is_url**

Mode: Retrieve only.

Whether this field was marked as being a URL (boolean).

Since: 1.99.8
fieldinfo.little_endian
Mode: Retrieve only.
Whether this field is little-endian encoded (boolean).
Since: 1.99.8

fieldinfo.big_endian
Mode: Retrieve only.
Whether this field is big-endian encoded (boolean).
Since: 1.99.8

fieldinfo.name
Mode: Retrieve only.
The filter name of this field.
Since: 1.99.8

Global Functions

all_field_infos()
Obtain all fields from the current tree. Note this only gets whatever fields the underlying dissectors have filled in for this packet at this time - there may be fields applicable to the packet that simply aren't being filled in because at this time they're not needed for anything. This function only gets what the C-side code has currently populated, not the full list.

Errors

• Cannot be called outside a listener or dissector

GUI support

ProgDlg
Manages a progress bar dialog.

ProgDlg.new([title], [task])
Creates a new ProgDlg progress dialog.

Arguments
title (optional)
Title of the new window, defaults to "Progress".

task (optional)
Current task, defaults to "".

Returns
The newly created ProgDlg object.

progdlg:update(progress, [task])
Appends text.

Arguments

progress
Part done (e.g. 0.75).

task (optional)
Current task, defaults to "".

Errors

• GUI not available
• Cannot be called for something not a ProgDlg
• Progress value out of range (must be between 0.0 and 1.0)

progdlg:stopped()
Checks whether the user has pressed the stop button.

Returns
true if the user has asked to stop the progress.

progdlg:close()
Closes the progress dialog.

Returns
A string specifying whether the Progress Dialog has stopped or not.

Errors

• GUI not available
TextWindow

Manages a text window.

TextWindow.new([title])

Creates a new TextWindow text window.

Arguments

title (optional)

Title of the new window.

Returns

The newly created TextWindow object.

Errors

• GUI not available

textwindow:set_atclose(action)

Set the function that will be called when the text window closes.

Arguments

action

A Lua function to be executed when the user closes the text window.

Returns

The TextWindow object.

Errors

• GUI not available

textwindow:set(text)

Sets the text.

Arguments

text

The text to be used.

Returns
The `TextWindow` object.

Errors

- GUI not available

`textwindow:append(text)`

Appends text

Arguments

text

  The text to be appended

Returns

The `TextWindow` object.

Errors

- GUI not available

`textwindow:prepend(text)`

Prepends text

Arguments

text

  The text to be appended

Returns

The `TextWindow` object.

Errors

- GUI not available

`textwindow:clear()`

Erases all text in the window.

Returns

The `TextWindow` object.
Errors

- GUI not available

textwindow:get_text()

Get the text of the window

Returns

The `TextWindow`'s text.

Errors

- GUI not available

textwindow:close()

Close the window

Errors

- GUI not available

textwindow:set_editable(editable)

Make this text window editable.

Arguments

editable (optional)

A boolean flag, defaults to true.

Returns

The `TextWindow` object.

Errors

- GUI not available

textwindow:add_button(label, function)

Adds a button to the text window.

Arguments

label
The label of the button

**function**

The Lua function to be called when clicked

**Returns**

The `TextWindow` object.

**Errors**

- GUI not available

**Global Functions**

**gui_enabled()**

Checks whether the GUI facility is enabled.

**Returns**

A boolean: true if it is enabled, false if it isn’t.

**register_menu(name, action, [group])**

Register a menu item in one of the main menus.

**Arguments**

**name**

The name of the menu item. The submenus are to be separated by `/`s. (string)

**action**

The function to be called when the menu item is invoked. (function taking no arguments and returning nothing)

**group (optional)**

The menu group into which the menu item is to be inserted. If omitted, defaults to `MENU_STAT_GENERIC`. One of:

- `MENU_STAT_UNSORTED` (Statistics),
- `MENU_STAT_GENERIC` (Statistics, first section),
- `MENU_STAT_CONVERSATION` (Statistics/Conversation List),
- `MENU_STAT_ENDPOINT` (Statistics/Endpoint List),
- `MENU_STAT_RESPONSE` (Statistics/Service Response Time),
• MENU_STAT_TELEPHONY (Telephony),
• MENU_STAT_TELEPHONY_ANSI (Telephony/ANSI),
• MENU_STAT_TELEPHONY_GSM (Telephony/GSM),
• MENU_STAT_TELEPHONY_LTE (Telephony/LTE),
• MENU_STAT_TELEPHONY_MTP3 (Telephony/MTP3),
• MENU_STAT_TELEPHONY_SCTP (Telephony/SCTP),
• MENU_ANALYZE (Analyze),
• MENU_ANALYZE_CONVERSATION (Analyze/Conversation Filter),
• MENU_TOOLS_UNSORTED (Tools). (number)

new_dialog(title, action, ...)

Pops up a new dialog

Arguments

title
  Title of the dialog's window.

action
  Action to be performed when OK'd.

...
  A series of strings to be used as labels of the dialog's fields.

Errors

• GUI not available
• At least one field required
• All fields must be strings

retap_packets()

Rescan all packets and just run taps - don't reconstruct the display.

copy_to_clipboard(text)

Copy a string into the clipboard.

Arguments

text
The string to be copied into the clipboard.

`open_capture_file(filename, filter)`

Open and display a capture file.

**Arguments**

`filename`

The name of the file to be opened.

`filter`

A filter to be applied as the file gets opened.

`get_filter()`

Get the main filter text.

`set_filter(text)`

Set the main filter text.

**Arguments**

`text`

The filter's text.

`set_color_filter_slot(row, text)`

Set packet-coloring rule for the current session.

**Arguments**

`row`

The index of the desired color in the temporary coloring rules list.

`text`

Display filter for selecting packets to be colorized.

`apply_filter()`

Apply the filter in the main filter box.

`reload()`

Reload the current capture file. Obsolete, use `reload_packets()`
reload_packets()
Reload the current capture file.

reload_lua_plugins()
Reload all Lua plugins.

browser_open_url(url)
Open an url in a browser.

Arguments
url
  The url.

browser_open_data_file(filename)
Open a file in a browser.

Arguments
filename
  The file name.

Post-dissection packet analysis

Listener
A Listener is called once for every packet that matches a certain filter or has a certain tap. It can read the tree, the packet's Tvb buffer as well as the tapped data, but it cannot add elements to the tree.

Listener.new([tap], [filter], [allfields])
Creates a new Listener listener object.

Arguments
tap (optional)
The name of this tap.

filter (optional)
A filter that when matches the tap.packet function gets called (use nil to be called for every packet).
allfields (optional)
  Whether to generate all fields. (default=false) Note: This impacts performance.

Returns
The newly created Listener listener object

Errors
  • tap registration error

Listener.list()

Gets a Lua array table of all registered Listener tap names.

Note: This is an expensive operation, and should only be used for troubleshooting.

Since: 1.11.3

Returns
The array table of registered tap names

listener:remove()

Removes a tap Listener.

listener:__tostring()

Generates a string of debug info for the tap Listener.

listener.packet

Mode: Assign only.

A function that will be called once every packet matches the Listener listener filter.

When later called by Wireshark, the packet function will be given:

1. A Pinfo object
2. A Tvb object
3. A tapinfo table

```plaintext
function tap.packet(pinfo, tvb, tapinfo) ... end
```

NOTE  tapinfo is a table of info based on the `Listener`'s type, or nil.
**listener.draw**

Mode: Assign only.

A function that will be called once every few seconds to redraw the GUI objects; in Tshark this function is called only at the very end of the capture file.

When later called by Wireshark, the `draw` function will not be given any arguments.

```plaintext
function tap.draw() ... end
```

**listener.reset**

Mode: Assign only.

A function that will be called at the end of the capture run.

When later called by Wireshark, the `reset` function will not be given any arguments.

```plaintext
function tap.reset() ... end
```

---

**Obtaining packet information**

**Address**

Represents an address.

**Address.ip(hostname)**

Creates an Address Object representing an IPv4 address.

**Arguments**

**hostname**

The address or name of the IP host.

**Returns**

The Address object.

**Address.ipv6(hostname)**

Creates an Address Object representing an IPv6 address.

**Arguments**
hostname

The address or name of the IP host.

Returns

The Address object

Address.ether(eth)

Creates an Address Object representing an Ethernet address.

Arguments

eth

The Ethernet address.

Returns

The Address object.

address:__tostring()

Returns

The string representing the address.

address:__eq()

Compares two Addresses.

address:__le()

Compares two Addresses.

address:__lt()

Compares two Addresses.

Column

A Column in the packet list.

column:__tostring()

Returns

The column’s string text (in parenthesis if not available).
column:clear()
Clears a Column.

column:set(text)
Sets the text of a Column.

Arguments
text
    The text to which to set the Column.

column:append(text)
Appends text to a Column.

Arguments
text
    The text to append to the Column.

column:prepend(text)
Prepends text to a Column.

Arguments
text
    The text to prepend to the Column.

column:fence()
Sets Column text fence, to prevent overwriting.

Since: 1.10.6

column:clear_fence()
Clear Column text fence.

Since: 1.11.3

Columns
The Columns of the packet list.
columns:__tostring()

Returns
The string "Columns", no real use, just for debugging purposes.

columns:__newindex(column, text)
Sets the text of a specific column.

Arguments

column
  The name of the column to set.

text
  The text for the column.

columns:__index()
Gets a specific Column.

**NSTime**

NSTime represents a nstime_t. This is an object with seconds and nanoseconds.

**NSTime.new([seconds], [nseconds])**
Creates a new NSTime object.

Arguments

seconds (optional)
  Seconds.

nseconds (optional)
  Nano seconds.

Returns
The new NSTime object.

**nstime:__call([seconds], [nseconds])**
Creates a NSTime object.

Arguments
seconds (optional)
  Seconds.

nseconds (optional)
  Nanoseconds.

Returns
The new NSTime object.

nstime:tonumber()
Returns a Lua number of the NSTime representing seconds from epoch

Since: 2.4.0

Returns
The Lua number.

nstime:_tostring()

Returns
The string representing the ntime.

nstime:_add()
Calculates the sum of two NSTimes.

nstime:_sub()
Calculates the diff of two NSTimes.

nstime:_unm()
Calculates the negative NSTime.

nstime:_eq()
Compares two NSTimes.

nstime:_le()
Compares two NSTimes.
**nsTime:** `__lt()`

Compares two NSTimes.

**nsTime.secs**

Mode: Retrieve or assign.

The NSTime seconds.

**nsTime.nsecs**

Mode: Retrieve or assign.

The NSTime nano seconds.

**Pinfo**

Packet information.

**pinfo.visited**

Mode: Retrieve only.

Whether this packet has been already visited.

**pinfo.number**

Mode: Retrieve only.

The number of this packet in the current file.

**pinfo.len**

Mode: Retrieve only.

The length of the frame.

**pinfo.caplen**

Mode: Retrieve only.

The captured length of the frame.

**pinfo.abs_ts**

Mode: Retrieve only.

When the packet was captured.
**pinfo.rel_ts**
Mode: Retrieve only.
Number of seconds passed since beginning of capture.

**pinfo.delta_ts**
Mode: Retrieve only.
Number of seconds passed since the last captured packet.

**pinfo.delta_dis_ts**
Mode: Retrieve only.
Number of seconds passed since the last displayed packet.

**pinfo.curr_proto**
Mode: Retrieve only.
Which Protocol are we dissecting.

**pinfo.can_desegment**
Mode: Retrieve or assign.
Set if this segment could be desegmented.

**pinfo.desegment_len**
Mode: Retrieve or assign.
Estimated number of additional bytes required for completing the PDU.

**pinfo.desegment_offset**
Mode: Retrieve or assign.
Offset in the tvbuff at which the dissector will continue processing when next called.

**pinfo.fragmented**
Mode: Retrieve only.
If the protocol is only a fragment.
pinfo.in_error_pkt
Mode: Retrieve only.
If we’re inside an error packet.

pinfo.match_uint
Mode: Retrieve only.
Matched uint for calling subdissector from table.

pinfo.match_string
Mode: Retrieve only.
Matched string for calling subdissector from table.

pinfo.port_type
Mode: Retrieve or assign.
Type of Port of .src_port and .dst_port.

pinfo.src_port
Mode: Retrieve or assign.
Source Port of this Packet.

pinfo.dst_port
Mode: Retrieve or assign.
Source Address of this Packet.

pinfo.dl_src
Mode: Retrieve or assign.
Data Link Source Address of this Packet.

pinfo.dl_dst
Mode: Retrieve or assign.
Data Link Destination Address of this Packet.
**pinfo.net_src**
Mode: Retrieve or assign.
Network Layer Source Address of this Packet.

**pinfo.net_dst**
Mode: Retrieve or assign.
Network Layer Destination Address of this Packet.

**pinfo.src**
Mode: Retrieve or assign.
Source Address of this Packet.

**pinfo.dst**
Mode: Retrieve or assign.
Destination Address of this Packet.

**pinfo.match**
Mode: Retrieve only.
Port/Data we are matching.

**pinfo.columns**
Mode: Retrieve only.
Access to the packet list columns.

**pinfo.cols**
Mode: Retrieve only.
Access to the packet list columns (equivalent to pinfo.columns).

**pinfo.private**
Mode: Retrieve only.
Access to the private table entries.
**pinfo.hi**

Mode: Retrieve or assign.

Higher Address of this Packet.

**pinfo.lo**

Mode: Retrieve only.

Lower Address of this Packet.

**pinfo.conversation**

Mode: Assign only.

Sets the packet conversation to the given Proto object.

### PrivateTable

PrivateTable represents the pinfo → private_table.

**privatetable:__tostring()**

Gets debugging type information about the private table.

**Returns**

A string with all keys in the table, mostly for debugging.

### Functions for new protocols and dissectors

The classes and functions in this chapter allow Lua scripts to create new protocols for Wireshark. Proto protocol objects can have *Pref* preferences, *ProtoField* fields for filterable values that can be displayed in a details view tree, functions for dissecting the new protocol, and so on.

The dissection function can be hooked into existing protocol tables through *DissectorTables* so that the new protocol dissector function gets called by that protocol, and the new dissector can itself call on other, already existing protocol dissectors by retrieving and calling the *Dissector* object. A Proto dissector can also be used as a post-dissector, at the end of every frame's dissection, or as a heuristic dissector.

### Dissector

A reference to a dissector, used to call a dissector against a packet or a part of it.
**Dissector.get(name)**

Obtains a dissector reference by name.

**Arguments**

**name**

The name of the dissector.

**Returns**

The Dissector reference.

**Dissector.list()**

Gets a Lua array table of all registered Dissector names.

Note: This is an expensive operation, and should only be used for troubleshooting.

Since: 1.11.3

**Returns**

The array table of registered dissector names.

**dissector:call(tvb, pinfo, tree)**

Calls a dissector against a given packet (or part of it).

**Arguments**

**tvb**

The buffer to dissect.

**pinfo**

The packet info.

**tree**

The tree on which to add the protocol items.

**Returns**

Number of bytes dissected. Note that some dissectors always return number of bytes in incoming buffer, so be aware.

**dissector:__call(tvb, pinfo, tree)**

Calls a dissector against a given packet (or part of it).
Arguments

tvb
   The buffer to dissect.

pinfo
   The packet info.

tree
   The tree on which to add the protocol items.

dissector:__tostring()

Gets the Dissector's protocol short name.

Returns

A string of the protocol's short name.

DissectorTable

A table of subdissectors of a particular protocol (e.g. TCP subdissectors like http, smtp, sip are added to table "tcp.port").

Useful to add more dissectors to a table so that they appear in the Decode As... dialog.

DissectorTable.new(tablename, [uiname], [type], [base], [proto])

Creates a new DissectorTable for your dissector's use.

Arguments

tablename
   The short name of the table.

uiname (optional)
   The name of the table in the User Interface (defaults to the name given).

type (optional)
   Either ftypes.UINT8, ftypes.UINT16, ftypes.UINT24, ftypes.UINT32, or ftypes.STRING (defaults to ftypes.UINT32).

base (optional)
   Either base.NONE, base.DEC, base.HEX, base.OCT, base.DEC_HEX or base.HEX_DEC (defaults to base.DEC).

proto (optional)
   The protocol that uses this dissector table (a Proto object).
Returns
The newly created DissectorTable.

DissectorTable.list()

Gets a Lua array table of all DissectorTable names - i.e., the string names you can use for the first argument to DissectorTable.get().

Note: This is an expensive operation, and should only be used for troubleshooting.

Since: 1.11.3

Returns
The array table of registered DissectorTable names.

DissectorTable.heuristic_list()

Gets a Lua array table of all heuristic list names - i.e., the string names you can use for the first argument in Proto:register_heuristic().

Note: This is an expensive operation, and should only be used for troubleshooting.

Since: 1.11.3

Returns
The array table of registered heuristic list names.

DissectorTable.get(tablename)

Obtain a reference to an existing dissector table.

Arguments

tablename
  The short name of the table.

Returns
The DissectorTable.

dissectortable:add(pattern, dissector)

Add a Proto with a dissector function, or a Dissector object, to the dissector table.

Arguments
**pattern**

The pattern to match (either an integer, a integer range or a string depending on the table’s type).

**dissector**

The dissector to add (either a `Proto` or a `Dissector`).

**dissectortable: set(pattern, dissector)**

Remove existing dissectors from a table and add a new or a range of new dissectors.

Since: 1.11.3

**Arguments**

**pattern**

The pattern to match (either an integer, a integer range or a string depending on the table’s type).

**dissector**

The dissector to add (either a `Proto` or a `Dissector`).

**dissectortable: remove(pattern, dissector)**

Remove a dissector or a range of dissectors from a table

**Arguments**

**pattern**

The pattern to match (either an integer, a integer range or a string depending on the table’s type).

**dissector**

The dissector to remove (either a `Proto` or a `Dissector`).

**dissectortable: remove_all(dissector)**

Remove all dissectors from a table.

Since: 1.11.3

**Arguments**

**dissector**

The dissector to remove (either a `Proto` or a `Dissector`).
dissectortable:try(pattern, tvb, pinfo, tree)

Try to call a dissector from a table

Arguments

pattern
The pattern to be matched (either an integer or a string depending on the table’s type).

tvb
The buffer to dissect.

pinfo
The packet info.

tree
The tree on which to add the protocol items.

Returns

Number of bytes dissected. Note that some dissectors always return number of bytes in incoming buffer, so be aware.

dissectortable:get_dissector(pattern)

Try to obtain a dissector from a table.

Arguments

pattern
The pattern to be matched (either an integer or a string depending on the table’s type).

Returns

The dissector handle if found.

nil if not found.

dissectortable:add_for_decode_as(proto)

Add the given Proto to the "Decode as..." list for this DissectorTable. The passed-in Proto object’s dissector() function is used for dissecting.

Since: 1.99.1

Arguments
proto
    The Proto to add.

dissectortable:_tostring()

Gets some debug information about the DissectorTable.

Returns
A string of debug information about the DissectorTable.

Pref
A preference of a Protocol.

Pref.bool(label, default, descr)
Creates a boolean preference to be added to a Proto.prefs Lua table.

Arguments
label
    The Label (text in the right side of the preference input) for this preference.

default
    The default value for this preference.

descr
    A description of what this preference is.

Pref.uint(label, default, descr)
Creates an (unsigned) integer preference to be added to a Proto.prefs Lua table.

Arguments
label
    The Label (text in the right side of the preference input) for this preference.

default
    The default value for this preference.

descr
    A description of what this preference is.
Pref.string(label, default, descr)

Creates a string preference to be added to a Proto.prefs Lua table.

Arguments

label
  The Label (text in the right side of the preference input) for this preference.

default
  The default value for this preference.

descr
  A description of what this preference is.

Pref.enum(label, default, descr, enum, radio)

Creates an enum preference to be added to a Proto.prefs Lua table.

Arguments

label
  The Label (text in the right side of the preference input) for this preference.

default
  The default value for this preference.

descr
  A description of what this preference is.

enum
  An enum Lua table.

radio
  Radio button (true) or Combobox (false).

Pref.range(label, default, descr, max)

Creates a range preference to be added to a Proto.prefs Lua table.

Arguments

label
  The Label (text in the right side of the preference input) for this preference.

default
The default value for this preference, e.g., "53", "10-30", or "10-30,53,55,100-120".

descr
A description of what this preference is.

max
The maximum value.

Pref.statictext(label, descr)
Creates a static text string to be added to a Proto.prefs Lua table.

Arguments

label
The static text.

descr
The static text description.

Prefs
The table of preferences of a protocol.

prefs:__newindex(name, pref)
Creates a new preference.

Arguments

name
The abbreviation of this preference.

pref
A valid but still unassigned Pref object.

Errors
- Unknown Pref type

prefs:__index(name)
Get the value of a preference setting.

Arguments
name
   The abbreviation of this preference.

Returns
The current value of the preference.

Errors
   • Unknown Pref type

Proto
A new protocol in Wireshark. Protocols have more uses, the main one is to dissect a protocol. But they can also be just dummies used to register preferences for other purposes.

Proto.new(name, desc)

Arguments
name
   The name of the protocol.

desc
   A Long Text description of the protocol (usually lowercase).

Returns
The newly created protocol.

proto:__call(name, desc)
Creates a Proto object.

Arguments
name
   The name of the protocol.

desc
   A Long Text description of the protocol (usually lowercase).

Returns
The new Proto object.
proto:register_heuristic(listname, func)

Registers a heuristic dissector function for this Proto protocol, for the given heuristic list name.

When later called, the passed-in function will be given:

1. A Tvb object
2. A Pinfo object
3. A TreeItem object

The function must return true if the payload is for it, else false.

The function should perform as much verification as possible to ensure the payload is for it, and dissect the packet (including setting TreeItem info and such) only if the payload is for it, before returning true or false.

Since version 1.99.1, this function also accepts a Dissector object as the second argument, to allow re-using the same Lua code as the function proto.dissector(...). In this case, the Dissector must return a Lua number of the number of bytes consumed/parsed: if 0 is returned, it will be treated the same as a false return for the heuristic; if a positive or negative number is returned, then the it will be treated the same as a true return for the heuristic, meaning the packet is for this protocol and no other heuristic will be tried.

Since: 1.11.3

Arguments

listname
- The heuristic list name this function is a heuristic for (e.g., "udp" or "infiniband.payload").

func
- A Lua function that will be invoked for heuristic dissection.

proto.dissector

Mode: Retrieve or assign.

The protocol’s dissector, a function you define.

When later called, the function will be given:

1. A Tvb object
2. A Pinfo object
3. A TreeItem object
proto.prefs
Mode: Retrieve only.
The preferences of this dissector.

proto.prefs_changed
Mode: Assign only.
The preferences changed routine of this dissector, a Lua function you define.

proto.init
Mode: Assign only.
The init routine of this dissector, a function you define.
The called init function is passed no arguments.

proto.name
Mode: Retrieve only.
The name given to this dissector.

proto.description
Mode: Retrieve only.
The description given to this dissector.

proto.fields
Mode: Retrieve or assign.
The `ProtoField`'s Lua table of this dissector.

proto.experts
Mode: Retrieve or assign.
The expert info Lua table of this Proto.
Since: 1.11.3

ProtoExpert
A Protocol expert info field, to be used when adding items to the dissection tree.
ProtoExpert.new(abbr, text, group, severity)

Creates a new ProtoExpert object to be used for a protocol’s expert information notices.

Since: 1.11.3

Arguments

abbr
Filter name of the expert info field (the string that is used in filters).

text
The default text of the expert field.

group
Expert group type: one of: expert.group.CHECKSUM, expert.group.SEQUENCE, expert.group.RESPONSE_CODE, expert.group.REQUEST_CODE, expert.group.UNDECODED, expert.group.REASSEMBLE, expert.group.MALFORMED, expert.group.DEBUG, expert.group.PROTOCOL, expert.group.SECURITY, expert.group.COMMENTS_GROUP or expert.group.DECRYPTION.

severity
Expert severity type: one of: expert.severity.COMMENT, expert.severity.CHAT, expert.severity.NOTE, expert.severity.WARN, or expert.severity.ERROR.

Returns

The newly created ProtoExpert object.

protoexpert:_tostring()

Returns a string with debugging information about a ProtoExpert object.

Since: 1.11.3

ProtoField

A Protocol field (to be used when adding items to the dissection tree).

ProtoField.new(name, abbr, type, [valuestring], [base], [mask], [descr])

Creates a new ProtoField object to be used for a protocol field.

Arguments

name
Actual name of the field (the string that appears in the tree).

**abbr**
Filter name of the field (the string that is used in filters).

**type**
Field Type: one of: `ftypes.BOOLEAN`, `ftypes.CHAR`, `ftypes.UINT8`, `ftypes.UINT16`, `ftypes.UINT24`, `ftypes.UINT32`, `ftypes.UINT64`, `ftypes.INT8`, `ftypes.INT16`, `ftypes.INT24`, `ftypes.INT32`, `ftypes.INT64`, `ftypes.FLOAT`, `ftypes.DOUBLE`, `ftypes.ABSOLUTE_TIME`, `ftypes.RELATIVE_TIME`, `ftypes.STRING`, `ftypes.STRINGZ`, `ftypes.UINT_STRING`, `ftypes.ETHER`, `ftypes.BYTES`, `ftypes.UINT_BYTES`, `ftypes.IPv4`, `ftypes.IPv6`, `ftypes.IPXNET`, `ftypes.FRAMENUM`, `ftypes.PCRE`, `ftypes.GUID`, `ftypes.OID`, `ftypes.PROTOCOL`, `ftypes.REL_OID`, `ftypes.SYSTEM_ID`, `ftypes.EUI64` or `ftypes.NONE`.

**valuestring (optional)**
A table containing the text that corresponds to the values, or a table containing tables of range string values that corresponds to the values ({min, max, "string"}) if the base is `base.RANGE_STRING`, or a table containing unit name for the values if base is `base.UNIT_STRING`, or one of `frametype.NONE`, `frametype.REQUEST`, `frametype.RESPONSE`, `frametype.ACK` or `frametype.DUP_ACK` if field type is `ftypes.FRAMENUM`.

**base (optional)**
The representation, one of: `base.NONE`, `base.DEC`, `base.HEX`, `base.OCT`, `base.DEC_HEX`, `base.HEX_DEC`, `base.UNIT_STRING` or `base.RANGE_STRING`.

**mask (optional)**
The bitmask to be used.

**descr (optional)**
The description of the field.

**Returns**
The newly created `ProtoField` object.

`ProtoField.char(abbr, [name], [base], [valuestring], [mask], [desc])`

Creates a `ProtoField` of an 8-bit ASCII character.

**Arguments**

**abbr**
Abbreviated name of the field (the string used in filters).

**name (optional)**
Actual name of the field (the string that appears in the tree).
base (optional)
One of base.NONE, base.HEX, base.OCT or base.RANGE_STRING.

valuestring (optional)
A table containing the text that corresponds to the values, or a table containing tables of range string values that correspond to the values ({min, max, "string"}) if the base is base.RANGE_STRING.

mask (optional)
Integer mask of this field.

desc (optional)
Description of the field.

Returns
A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.uint8(abbr, [name], [base], [valuestring], [mask], [desc])
Creates a ProtoField of an unsigned 8-bit integer (i.e., a byte).

Arguments
abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

base (optional)
One of base.DEC, base.HEX or base.OCT, base.DEC_HEX, base.HEX_DEC, base.UNIT_STRING or base.RANGE_STRING.

valuestring (optional)
A table containing the text that corresponds to the values, or a table containing tables of range string values that correspond to the values ({min, max, "string"}) if the base is base.RANGE_STRING, or a table containing the unit name for the values if base is base.UNIT_STRING.

mask (optional)
Integer mask of this field.

desc (optional)
Description of the field.

Returns
A **ProtoField** object to be added to a table set to the **Proto.fields** attribute.

**ProtoField.uint16(abbr, [name], [base], [valuestring], [mask], [desc])**

Creates a **ProtoField** of an unsigned 16-bit integer.

**Arguments**

**abbr**

Abbreviated name of the field (the string used in filters).

**name (optional)**

Actual name of the field (the string that appears in the tree).

**base (optional)**

One of **base.DEC**, **base.HEX**, **base.OCT**, **base.DEC_HEX**, **base.HEX_DEC**, **base.UNIT_STRING** or **base.RANGE_STRING**.

**valuestring (optional)**

A table containing the text that corresponds to the values, or a table containing tables of range string values that correspond to the values ({min, max, "string"}) if the base is **base.RANGE_STRING**, or a table containing unit name for the values if base is **base.UNIT_STRING**.

**mask (optional)**

Integer mask of this field.

**desc (optional)**

Description of the field.

**Returns**

A **ProtoField** object to be added to a table set to the **Proto.fields** attribute.

**ProtoField.uint24(abbr, [name], [base], [valuestring], [mask], [desc])**

Creates a **ProtoField** of an unsigned 24-bit integer.

**Arguments**

**abbr**

Abbreviated name of the field (the string used in filters).

**name (optional)**

Actual name of the field (the string that appears in the tree).

**base (optional)**
One of base.DEC, base.HEX, base.OCT, base.DEC_HEX, base.HEX_DEC, base.UNIT_STRING, or base.RANGE_STRING.

valuestring (optional)
A table containing the text that corresponds to the values, or a table containing tables of range string values that correspond to the values ({min, max, “string”}) if the base is base.RANGE_STRING, or a table containing the unit name for the values if base is base.UNIT_STRING.

mask (optional)
Integer mask of this field.

desc (optional)
Description of the field.

Returns
A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.uint32(abbr, [name], [base], [valuestring], [mask], [desc])
Creates a ProtoField of an unsigned 32-bit integer.

Arguments
abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

base (optional)
One of base.DEC, base.HEX, base.OCT, base.DEC_HEX, base.HEX_DEC, base.UNIT_STRING, or base.RANGE_STRING.

valuestring (optional)
A table containing the text that corresponds to the values, or a table containing tables of range string values that correspond to the values ({min, max, “string”}) if the base is base.RANGE_STRING, or a table containing the unit name for the values if base is base.UNIT_STRING.

mask (optional)
Integer mask of this field.

desc (optional)
Description of the field.

Returns
A `ProtoField` object to be added to a table set to the `Proto.fields` attribute.

```python
ProtoField.uint64(abbr, [name], [base], [valuestring], [mask], [desc])
```

Creates a `ProtoField` of an unsigned 64-bit integer.

**Arguments**

`abbr`

Abbreviated name of the field (the string used in filters).

`name (optional)`

Actual name of the field (the string that appears in the tree).

`base (optional)`

One of `base.DEC`, `base.HEX`, `base.OCT`, `base.DEC_HEX`, `base.HEX_DEC`, `base.UNIT_STRING`, or `base.RANGE_STRING`.

`valuestring (optional)`

A table containing the text that corresponds to the values, or a table containing tables of range string values that correspond to the values ({min, max, "string") if the base is `base.RANGE_STRING`, or a table containing the unit name for the values if base is `base.UNIT_STRING`.

`mask (optional)`

Integer mask of this field.

`desc (optional)`

Description of the field.

**Returns**

A `ProtoField` object to be added to a table set to the `Proto.fields` attribute.

```python
ProtoField.int8(abbr, [name], [base], [valuestring], [mask], [desc])
```

Creates a `ProtoField` of a signed 8-bit integer (i.e., a byte).

**Arguments**

`abbr`

Abbreviated name of the field (the string used in filters).

`name (optional)`

Actual name of the field (the string that appears in the tree).

`base (optional)`
One of \texttt{base.DEC}, \texttt{base.UNIT STRING}, or \texttt{base.RANGE STRING}.

\begin{description}
\item[\texttt{valuestring (optional)}]
A table containing the text that corresponds to the values, or a table containing tables of range string values that correspond to the values ({min, max, "string"}) if the base is \texttt{base.RANGE STRING}, or a table containing unit name for the values if base is \texttt{base.UNIT STRING}.
\item[\texttt{mask (optional)}]
Integer mask of this field.
\item[\texttt{desc (optional)}]
Description of the field.
\end{description}

\textbf{Returns}

A \texttt{ProtoField} object to be added to a table set to the \texttt{Proto.fields} attribute.

\begin{verbatim}
ProtoField.int16(abbr, [name], [base], [valuestring], [mask], [desc])
\end{verbatim}

Creates a \texttt{ProtoField} of a signed 16-bit integer.

\begin{description}
\item[\texttt{abbr}]
Abbreviated name of the field (the string used in filters).
\item[\texttt{name (optional)}]
Actual name of the field (the string that appears in the tree).
\item[\texttt{base (optional)}]
One of \texttt{base.DEC}, \texttt{base.UNIT STRING}, or \texttt{base.RANGE STRING}.
\item[\texttt{valuestring (optional)}]
A table containing the text that corresponds to the values, or a table containing tables of range string values that correspond to the values ({min, max, "string"}) if the base is \texttt{base.RANGE STRING}, or a table containing unit name for the values if base is \texttt{base.UNIT STRING}.
\item[\texttt{mask (optional)}]
Integer mask of this field.
\item[\texttt{desc (optional)}]
Description of the field.
\end{description}

\textbf{Returns}

A \texttt{ProtoField} object to be added to a table set to the \texttt{Proto.fields} attribute.
ProtoField.int24(abbr, [name], [base], [valuestring], [mask], [desc])

Creates a ProtoField of a signed 24-bit integer.

Arguments

abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

base (optional)
One of base.DEC, base.UNIT_STRING, or base.RANGE_STRING.

valuestring (optional)
A table containing the text that corresponds to the values, or a table containing tables of range string values that correspond to the values ({min, max, "string"}) if the base is base.RANGE_STRING, or a table containing unit name for the values if base is base.UNIT_STRING.

mask (optional)
Integer mask of this field.

desc (optional)
Description of the field.

Returns

A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.int32(abbr, [name], [base], [valuestring], [mask], [desc])

Creates a ProtoField of a signed 32-bit integer.

Arguments

abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

base (optional)
One of base.DEC, base.UNIT_STRING, or base.RANGE_STRING.

valuestring (optional)
A table containing the text that corresponds to the values, or a table containing tables of range string values that correspond to the values ({min, max, "string"}) if the base is `base.RANGE_STRING`, or a table containing unit name for the values if base is `base.UNIT_STRING`.

**mask (optional)**
Integer mask of this field.

**desc (optional)**
Description of the field.

**Returns**
A `ProtoField` object to be added to a table set to the `Proto.fields` attribute.

`ProtoField.int64(abbr, [name], [base], [valuestring], [mask], [desc])`

Creates a `ProtoField` of a signed 64-bit integer.

**Arguments**

**abbr**
Abbreviated name of the field (the string used in filters).

**name (optional)**
Actual name of the field (the string that appears in the tree).

**base (optional)**
One of `base.DEC`, `base.UNIT_STRING`, or `base.RANGE_STRING`.

**valuestring (optional)**
A table containing the text that corresponds to the values, or a table containing tables of range string values that correspond to the values ({min, max, "string"}) if the base is `base.RANGE_STRING`, or a table containing unit name for the values if base is `base.UNIT_STRING`.

**mask (optional)**
Integer mask of this field.

**desc (optional)**
Description of the field.

**Returns**
A `ProtoField` object to be added to a table set to the `Proto.fields` attribute.
ProtoField.framenum(abbr, [name], [base], [frametype], [mask], [desc])

Creates a ProtoField for a frame number (for hyperlinks between frames).

Arguments

abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

base (optional)
Only base.NONE is supported for framenum.

frametype (optional)
One of frametype.NONE, frametype.REQUEST, frametype.RESPONSE, frametype.ACK or frametype.DUP_ACK.

mask (optional)
Integer mask of this field, which must be 0 for framenum.

desc (optional)
Description of the field.

Returns

A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.bool(abbr, [name], [display], [valuestring], [mask], [desc])

Creates a ProtoField for a boolean true/false value.

Arguments

abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

display (optional)
How wide the parent bitfield is (base.NONE is used for NULL-value).

valuestring (optional)
A table containing the text that corresponds to the values.
mask (optional)
    Integer mask of this field.

desc (optional)
    Description of the field.

Returns

A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.absolute_time(abbr, [name], [base], [desc])

Creates a ProtoField of a time_t structure value.

Arguments

abbr
    Abbreviated name of the field (the string used in filters).

name (optional)
    Actual name of the field (the string that appears in the tree).

base (optional)
    One of base.LOCAL, base.UTC or base.DOY.UTC.

desc (optional)
    Description of the field.

Returns

A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.relative_time(abbr, [name], [desc])

Creates a ProtoField of a time_t structure value.

Arguments

abbr
    Abbreviated name of the field (the string used in filters).

name (optional)
    Actual name of the field (the string that appears in the tree).

desc (optional)
    Description of the field.
Returns

A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.float(abbr, [name], [valuestring], [desc])

Creates a ProtoField of a floating point number (4 bytes).

Arguments

abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

valuestring (optional)
A table containing unit name for the values.

desc (optional)
Description of the field.

Returns

A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.double(abbr, [name], [valuestring], [desc])

Creates a ProtoField of a double-precision floating point (8 bytes).

Arguments

abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

valuestring (optional)
A table containing unit name for the values.

desc (optional)
Description of the field.

Returns

A ProtoField object to be added to a table set to the Proto.fields attribute.
ProtoField.string(abbr, [name], [display], [desc])

Creates a ProtoField of a string value.

Arguments

abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

display (optional)
One of base.ASCII or base.UNICODE.

desc (optional)
Description of the field.

Returns

A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.stringz(abbr, [name], [display], [desc])

Creates a ProtoField of a zero-terminated string value.

Arguments

abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

display (optional)
One of base.ASCII or base.UNICODE.

desc (optional)
Description of the field.

Returns

A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.bytes(abbr, [name], [display], [desc])

Creates a ProtoField for an arbitrary number of bytes.
Arguments

abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

display (optional)
One of base.NONE, base.DOT, base.DASH, base.COLON or base.SPACE.

desc (optional)
Description of the field.

Returns

A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.abytes(abbr, [name], [display], [desc])
Creates a ProtoField for an arbitrary number of unsigned bytes.

Arguments

abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

display (optional)
One of base.NONE, base.DOT, base.DASH, base.COLON or base.SPACE.

desc (optional)
Description of the field.

Returns

A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.none(abbr, [name], [desc])
Creates a ProtoField of an unstructured type.

Arguments
**abbr**

Abbreviated name of the field (the string used in filters).

**name (optional)**

Actual name of the field (the string that appears in the tree).

**desc (optional)**

Description of the field.

**Returns**

A `ProtoField` object to be added to a table set to the `Proto.fields` attribute.

`ProtoField.ipv4(abbr, [name], [desc])`

Creates a `ProtoField` of an IPv4 address (4 bytes).

**Arguments**

**abbr**

Abbreviated name of the field (the string used in filters).

**name (optional)**

Actual name of the field (the string that appears in the tree).

**desc (optional)**

Description of the field.

**Returns**

A `ProtoField` object to be added to a table set to the `Proto.fields` attribute.

`ProtoField.ipv6(abbr, [name], [desc])`

Creates a `ProtoField` of an IPv6 address (16 bytes).

**Arguments**

**abbr**

Abbreviated name of the field (the string used in filters).

**name (optional)**

Actual name of the field (the string that appears in the tree).

**desc (optional)**

Description of the field.
Returns
A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.ether(abbr, [name], [desc])
Creates a ProtoField of an Ethernet address (6 bytes).

Arguments
abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

desc (optional)
Description of the field.

Returns
A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.guid(abbr, [name], [desc])
Creates a ProtoField for a Globally Unique IDentifier (GUID).

Arguments
abbr
Abbreviated name of the field (the string used in filters).

name (optional)
Actual name of the field (the string that appears in the tree).

desc (optional)
Description of the field.

Returns
A ProtoField object to be added to a table set to the Proto.fields attribute.

ProtoField.oid(abbr, [name], [desc])
Creates a ProtoField for an ASN.1 Organizational IDentified (OID).

Arguments
**abbr**
Abbreviated name of the field (the string used in filters).

**name (optional)**
Actual name of the field (the string that appears in the tree).

**desc (optional)**
Description of the field.

**Returns**
A `ProtoField` object to be added to a table set to the `Proto.fields` attribute.

**ProtoField.protocol(abbr, [name], [desc])**
Creates a `ProtoField` for a sub-protocol. Since 1.99.9.

**Arguments**

**abbr**
Abbreviated name of the field (the string used in filters).

**name (optional)**
Actual name of the field (the string that appears in the tree).

**desc (optional)**
Description of the field.

**Returns**
A `ProtoField` object to be added to a table set to the `Proto.fields` attribute.

**ProtoField.rel_oid(abbr, [name], [desc])**
Creates a `ProtoField` for an ASN.1 Relative-OID.

**Arguments**

**abbr**
Abbreviated name of the field (the string used in filters).

**name (optional)**
Actual name of the field (the string that appears in the tree).

**desc (optional)**
Description of the field.
Returns

A `ProtoField` object to be added to a table set to the `Proto.fields` attribute.

`ProtoField.systemid(abbr, [name], [desc])`

Creates a `ProtoField` for an OSI System ID.

**Arguments**

`abbr`

Abbreviated name of the field (the string used in filters).

`name (optional)`

Actual name of the field (the string that appears in the tree).

`desc (optional)`

Description of the field.

Returns

A `ProtoField` object to be added to a table set to the `Proto.fields` attribute.

`ProtoField.eui64(abbr, [name], [desc])`

Creates a `ProtoField` for an EUI64.

**Arguments**

`abbr`

Abbreviated name of the field (the string used in filters).

`name (optional)`

Actual name of the field (the string that appears in the tree).

`desc (optional)`

Description of the field.

Returns

A `ProtoField` object to be added to a table set to the `Proto.fields` attribute.

`protofield:__tostring()`

Returns a string with info about a protofield (for debugging purposes).
Global Functions

register_postdissector(proto, [allfields])

Make a Proto protocol (with a dissector function) a post-dissector. It will be called for every frame after dissection.

Arguments

proto
   The protocol to be used as post-dissector.

allfields (optional)
   Whether to generate all fields. Note: This impacts performance (default=false).

dissect_tcp_pdus(tvb, tree, min_header_size, get_len_func, dissect_func, [desequent])

Make the TCP-layer invoke the given Lua dissection function for each PDU in the TCP segment, of the length returned by the given get_len_func function.

This function is useful for protocols that run over TCP and that are either a fixed length always, or have a minimum size and have a length field encoded within that minimum portion that identifies their full length. For such protocols, their protocol dissector function can invoke this dissect_tcp_pdus() function to make it easier to handle dissecting their protocol's messages (i.e., their protocol data unit (PDU)). This function should not be used for protocols whose PDU length cannot be determined from a fixed minimum portion, such as HTTP or Telnet.

Since: 1.99.2

Arguments

tvb
   The Tvb buffer to dissect PDUs from.

tree
   The Tvb buffer to dissect PDUs from.

min_header_size
   The number of bytes in the fixed-length part of the PDU.

get_len_func
   A Lua function that will be called for each PDU, to determine the full length of the PDU. The called function will be given (1) the Tvb object of the whole Tvb (possibly reassembled), (2) the Pinfo object, and (3) an offset number of the index of the first byte of the PDU (i.e., its first header byte). The Lua function must return a Lua number of the full length of the PDU.
dissect_func

A Lua function that will be called for each PDU, to dissect the PDU. The called function will be given (1) the Tvb object of the PDU’s Tvb (possibly reassembled), (2) the Pinfo object, and (3) the TreeItem object. The Lua function must return a Lua number of the number of bytes read/handled, which would typically be the Tvb:len().

desegment (optional)

Whether to reassemble PDUs crossing TCP segment boundaries or not. (default=true)

Adding information to the dissection tree

TreeItem

TreeItems represent information in the packet-details pane of Wireshark, and the packet details view of Tshark. A TreeItem represents a node in the tree, which might also be a subtree and have a list of children. The children of a subtree have zero or more siblings: other children of the same TreeItem subtree.

During dissection, heuristic-dissection, and post-dissection, a root TreeItem is passed to dissectors as the third argument of the function callback (e.g., myproto.dissector(tvb, pktinfo, root)).

In some cases the tree is not truly added to, in order to improve performance. For example for packets not currently displayed/selected in Wireshark’s visible window pane, or if Tshark isn’t invoked with the -V switch. However the "add" type TreeItem functions can still be called, and still return TreeItem objects - but the info isn’t really added to the tree. Therefore you do not typically need to worry about whether there’s a real tree or not. If, for some reason, you need to know it, you can use the tree.visible attribute getter to retrieve the state.

treeitem:add_packet_field(protofield, [tvbrange], encoding, [label])

Adds a new child tree for the given ProtoField object to this tree item, returning the new child TreeItem.

Unlike TreeItem:add() and TreeItem:add_le(), the ProtoField argument is not optional, and cannot be a Proto object. Instead, this function always uses the ProtoField to determine the type of field to extract from the passed-in TvbRange, highlighting the relevant bytes in the Packet Bytes pane of the GUI (if there is a GUI), etc. If no TvbRange is given, no bytes are highlighted and the field’s value cannot be determined; the ProtoField must have been defined/created not to have a length in such a case, or an error will occur. For backwards-compatibility reasons the encoding argument, however, must still be given.

Unlike TreeItem:add() and TreeItem:add_le(), this function performs both big-endian and little-endian decoding, by setting the encoding argument to be ENC_BIG_ENDIAN or ENC_LITTLE_ENDIAN.

The signature of this function:
In Wireshark version 1.11.3, this function was changed to return more than just the new child `TreeItem`. The child is the first return value, so that function chaining will still work as before; but it now also returns the value of the extracted field (i.e., a number, `UInt64`, `Address`, etc.). If the value could not be extracted from the `TvbRange`, the child `TreeItem` is still returned, but the second returned value is `nil`.

Another new feature added to this function in Wireshark version 1.11.3 is the ability to extract native number `ProtoField`'s from string encoding in the `TvbRange`, for ASCII-based and similar string encodings. For example, a `ProtoField` of as `ftypes UINT32` type can be extracted from a `TvbRange` containing the ASCII string "123", and it will correctly decode the ASCII to the number `123`, both in the tree as well as for the second return value of this function. To do so, you must set the `encoding` argument of this function to the appropriate string `ENC_*` value, bitwise-or'd with the `ENC_STRING` value (see `init.lua`). `ENC_STRING` is guaranteed to be a unique bit flag, and thus it can added instead of bitwise-or'ed as well. Only single-byte ASCII digit string encoding types can be used for this, such as `ENC_ASCII` and `ENC_UTF_8`.

For example, assuming the `Tvb` named “tvb” contains the string "123":

```lua
-- this is done earlier in the script
local myfield = ProtoField.new("Transaction ID", "myproto.trans_id", ftypes.UINT16)

-- this is done inside a dissector, post-dissector, or heuristic function
-- child will be the created child tree, and value will be the number 123 or nil on failure
local child, value = tree:add_packet_field(myfield, tvb:range(0,3), ENC_UTF_8 + ENC_STRING)
```

**Arguments**

**protofield**

The `ProtoField` field object to add to the tree.

**tvbrange (optional)**

The `TvbRange` of bytes in the packet this tree item covers/represents.

**encoding**

The field’s encoding in the `TvbRange`.

**label (optional)**

One or more strings to append to the created `TreeItem`. 
Returns
The new child `TreeItem`, the field’s extracted value or nil, and offset or nil.

treeitem:add([protofield], [tvrange], [value], [label])

Adds a child item to this tree item, returning the new child `TreeItem`.

If the `ProtoField` represents a numeric value (int, uint or float), then it’s treated as a Big Endian (network order) value.

This function has a complicated form: 'treeitem:add([protofield,] [tvrange,] value[), label)', such that if the first argument is a `ProtoField` or a `Proto`, the second argument is a `TvbRange`, and a third argument is given, it’s a value; but if the second argument is a non-`TvbRange`, then it’s the value (as opposed to filling that argument with 'nil', which is invalid for this function). If the first argument is a non-`ProtoField` and a non-`Proto` then this argument can be either a `TvbRange` or a label, and the value is not in use.

Arguments

protofield (optional)
- The ProtoField field or Proto protocol object to add to the tree.

tvbrange (optional)
- The TvbRange of bytes in the packet this tree item covers/represents.

value (optional)
- The field’s value, instead of the ProtoField/Proto one.

label (optional)
- One or more strings to use for the tree item label, instead of the ProtoField/Proto one.

Returns
The new child TreeItem.

treeitem:add_le([protofield], [tvrange], [value], [label])

Adds a child item to this tree item, returning the new child `TreeItem`.

If the `ProtoField` represents a numeric value (int, uint or float), then it’s treated as a Little Endian value.

This function has a complicated form: 'treeitem:add_le([protofield,] [tvrange,] value[), label)', such that if the first argument is a `ProtoField` or a `Proto`, the second argument is a `TvbRange`, and a third argument is given, it’s a value; but if the second argument is a non-`TvbRange`, then it’s the value (as opposed to filling that argument with 'nil', which is invalid for this function). If the first argument is
a non-ProtoField and a non-Proto then this argument can be either a TvbRange or a label, and the value is not in use.

**Arguments**

**protofield (optional)**
- The ProtoField field or Proto protocol object to add to the tree.

**tvbrange (optional)**
- The TvbRange of bytes in the packet this tree item covers/represents.

**value (optional)**
- The field's value, instead of the ProtoField/Proto one.

**label (optional)**
- One or more strings to use for the tree item label, instead of the ProtoField/Proto one.

**Returns**

The new child TreeItem.

**treeitem:set_text(text)**

Sets the text of the label.

This used to return nothing, but as of 1.11.3 it returns the same tree item to allow chained calls.

**Arguments**

**text**
- The text to be used.

**Returns**

The same TreeItem.

**treeitem:append_text(text)**

Appends text to the label.

This used to return nothing, but as of 1.11.3 it returns the same tree item to allow chained calls.

**Arguments**

**text**
- The text to be appended.
Returns
The same TreeItem.

treeitem:prepend_text(text)
Prepends text to the label.

This used to return nothing, but as of 1.11.3 it returns the same tree item to allow chained calls.

Arguments
text
    The text to be prepended.

Returns
The same TreeItem.

treeitem:add_expert_info([group], [severity], [text])
Sets the expert flags of the item and adds expert info to the packet.

This function does not create a truly filterable expert info for a protocol. Instead you should use TreeItem.add_proto_expert_info().

Note: This function is provided for backwards compatibility only, and should not be used in new Lua code. It may be removed in the future. You should only use TreeItem.add_proto_expert_info().

Arguments
group (optional)
    One of PI_CHECKSUM, PI_SEQUENCE, PI_RESPONSE_CODE, PI_REQUEST_CODE, PI_UNDECODED, PI_REASSEMBLE, PI_MALFORMED or PI_DEBUG.

severity (optional)
    One of PI_CHAT, PI_NOTE, PI_WARN, or PI_ERROR.

text (optional)
    The text for the expert info display.

Returns
The same TreeItem.

treeitem:add_proto_expert_info(expert, [text])
Sets the expert flags of the tree item and adds expert info to the packet.
Since: 1.11.3

Arguments

`expert`

The `ProtoExpert` object to add to the tree.

`text (optional)`

Text for the expert info display (default is to use the registered text).

Returns

The same `TreeItem`.

`treeitem:add tvb_expert_info(expert, tvb, [text])`

Sets the expert flags of the tree item and adds expert info to the packet associated with the `Tvb` or `TvbRange` bytes in the packet.

Since: 1.11.3

Arguments

`expert`

The `ProtoExpert` object to add to the tree.

`tvb`

The `Tvb` or `TvbRange` object bytes to associate the expert info with.

`text (optional)`

Text for the expert info display (default is to use the registered text).

Returns

The same `TreeItem`.

`treeitem:set_generated([bool])`

Marks the `TreeItem` as a generated field (with data inferred but not contained in the packet).

This used to return nothing, but as of 1.11.3 it returns the same tree item to allow chained calls.

Arguments

`bool (optional)`

A Lua boolean, which if `true` sets the `TreeItem` generated flag, else clears it (default=true)
Returns
The same TreeItem.

treeitem:set_hidden([bool])
Marks the TreeItem as a hidden field (neither displayed nor used in filters).
This used to return nothing, but as of 1.11.3 it returns the same tree item to allow chained calls.

Arguments

bool (optional)
A Lua boolean, which if true sets the TreeItem hidden flag, else clears it (default=true)

Returns
The same TreeItem.

treeitem:set_len(len)
Set `TreeItem's length inside tvb, after it has already been created.
This used to return nothing, but as of 1.11.3 it returns the same tree item to allow chained calls.

Arguments

len
The length to be used.

Returns
The same TreeItem.

treeitem:referenced(protofield)
Checks if a ProtoField or Dissector is referenced by a filter/tap/UI.

If this function returns FALSE, it means that the field (or dissector) does not need to be dissected and can be safely skipped. By skipping a field rather than dissecting it, the dissector will usually run faster since Wireshark will not do extra dissection work when it doesn't need the field.

You can use this in conjunction with the TreeItem.visible attribute. This function will always return TRUE when the TreeItem is visible. When it is not visible and the field is not referenced, you can speed up the dissection by not dissecting the field as it is not needed for display or filtering.

This function takes one parameter that can be a ProtoField or a Dissector. The Dissector form is useful when you need to decide whether to call a sub-dissector.
Since: 2.4.0

**Arguments**

**protofield**

The ProtoField or Dissector to check if referenced.

**Returns**

A boolean indicating if the ProtoField/Dissector is referenced

**treeitem:** __tostring()

Returns string debug information about the TreeItem.

Since: 1.99.8

**treeitem.text**

Mode: Retrieve or assign.

Set/get the TreeItem's display string (string).

For the getter, if the TreeItem has no display string, then nil is returned.

Since: 1.99.3

**treeitem.visible**

Mode: Retrieve only.

Get the TreeItem's subtree visibility status (boolean).

Since: 1.99.8

**treeitem.generated**

Mode: Retrieve or assign.

Set/get the TreeItem's generated state (boolean).

Since: 1.99.8

**treeitem.hidden**

Mode: Retrieve or assign.

Set/get TreeItem's hidden state (boolean).
treeitem.len

Mode: Retrieve or assign.

Set/get `TreeItem's length inside tvb, after it has already been created.

Since: 1.99.8

Functions for handling packet data

ByteArray

ByteArray.new([hexbytes], [separator])

Creates a ByteArray object.

Starting in version 1.11.3, if the second argument is a boolean true, then the first argument is treated as a raw Lua string of bytes to use, instead of a hexadecimal string.

Arguments

hexbytes (optional)
A string consisting of hexadecimal bytes like "00 B1 A2" or "1a2b3c4d".

separator (optional)
A string separator between hex bytes/words (default=" "), or if the boolean value true is used, then the first argument is treated as raw binary data

Returns

The new ByteArray object.

bytearray:__concat(first, second)

Concatenate two ByteArrays.

Arguments

first
First array.

second
Second array.
Returns

The new composite \texttt{ByteArray}.

\texttt{bytearray:__eq(first, second)}

Compares two \texttt{ByteArray} values.

Since: 1.11.4

Arguments

\texttt{first}

First array.

\texttt{second}

Second array.

\texttt{bytearray:prepend(prepended)}

Prepend a \texttt{ByteArray} to this \texttt{ByteArray}.

Arguments

\texttt{prepended}

\texttt{ByteArray} to be prepended.

\texttt{bytearray:append(appended)}

Append a \texttt{ByteArray} to this \texttt{ByteArray}.

Arguments

\texttt{appended}

\texttt{ByteArray} to be appended.

\texttt{bytearray:set_size(size)}

Sets the size of a \texttt{ByteArray}, either truncating it or filling it with zeros.

Arguments

\texttt{size}

New size of the array.

Errors

- \texttt{ByteArray size must be non-negative}
bytearray:set_index(index, value)
Sets the value of an index of a ByteArray.

Arguments
index
The position of the byte to be set.
value
The char value to set [0-255].

bytearray:get_index(index)
Get the value of a byte in a ByteArray.

Arguments
index
The position of the byte to get.

Returns
The value [0-255] of the byte.

bytearray:len()
Obtain the length of a ByteArray.

Returns
The length of the ByteArray.

bytearray:subset(offset, length)
Obtain a segment of a ByteArray, as a new ByteArray.

Arguments
offset
The position of the first byte (0=first).
length
The length of the segment.

Returns
A ByteArray containing the requested segment.
bytearray:base64_decode()
Obtain a Base64 decoded ByteArray.

Since: 1.11.3

Returns
The created ByteArray.

bytearray:raw([offset], [length])
Obtain a Lua string of the binary bytes in a ByteArray.

Since: 1.11.3

Arguments

offset (optional)
The position of the first byte (default=0/first).

length (optional)
The length of the segment to get (default=all).

Returns
A Lua string of the binary bytes in the ByteArray.

bytearray:tohex([lowercase], [separator])
Obtain a Lua string of the bytes in a ByteArray as hex-ascii, with given separator

Since: 1.11.3

Arguments

lowercase (optional)
True to use lower-case hex characters (default=false).

separator (optional)
A string separator to insert between hex bytes (default=nil).

Returns
A hex-ascii string representation of the ByteArray.
bytearray:__tostring()

Obtain a Lua string containing the bytes in a ByteArray so that it can be used in display filters (e.g. "01FE456789AB").

Returns

A hex-ascii string representation of the ByteArray.

bytearray:tvb(name)

Creates a new Tvb from a ByteArray (it gets added to the current frame too).

Arguments

name

The name to be given to the new data-source.

Returns

The created Tvb.

Tvb

A Tvb represents the packet's buffer. It is passed as an argument to listeners and dissectors, and can be used to extract information (via TvbRange) from the packet's data.

To create a TvbRange the Tvb must be called with offset and length as optional arguments; the offset defaults to 0 and the length to tvb:len().

WARNING

Tvbs are usable only by the current listener or dissector call and are destroyed as soon as the listener/dissector returns, so references to them are unusable once the function has returned.

tvb:__tostring()

Convert the bytes of a Tvb into a string, to be used for debugging purposes, as '...' will be appended if the string is too long.

Returns

The string.

tvb:reported_len()

Obtain the reported (not captured) length of a Tvb.
**Returns**
The reported length of the Tvb.

**tvb:len()**
Obtain the actual (captured) length of a Tvb.

**Returns**
The captured length of the Tvb.

**tvb:reported_length_remaining()**
Obtain the reported (not captured) length of packet data to end of a Tvb or -1 if the offset is beyond the end of the Tvb.

**Returns**
The captured length of the Tvb.

**tvb:bytes([offset], [length])**
Obtain a ByteArray from a Tvb.

Since: 1.99.8

**Arguments**

**offset (optional)**
The offset (in octets) from the beginning of the Tvb. Defaults to 0.

**length (optional)**
The length (in octets) of the range. Defaults to until the end of the Tvb.

**Returns**
The ByteArray object or nil.

**tvb:offset()**
Returns the raw offset (from the beginning of the source Tvb) of a sub Tvb.

**Returns**
The raw offset of the Tvb.
tvb:__call()
Equivalent to tvb:range(…)

tvb:range([offset], [length])
Creates a TvbRange from this Tvb.

Arguments

offset (optional)
The offset (in octets) from the beginning of the Tvb. Defaults to 0.

length (optional)
The length (in octets) of the range. Defaults to until the end of the Tvb.

Returns
The TvbRange

tvb:raw([offset], [length])
Obtain a Lua string of the binary bytes in a Tvb.

Since: 1.11.3

Arguments

offset (optional)
The position of the first byte (default=0/first).

length (optional)
The length of the segment to get (default=all).

Returns
A Lua string of the binary bytes in the Tvb.

tvb:__eq()
Checks whether the two Tvb contents are equal.

Since: 1.99.8

**TvbRange**

A TvbRange represents a usable range of a Tvb and is used to extract data from the Tvb that generated it.
TvRange's are created by calling a `Tvb` (e.g. `tvb(offset,length)`). If the TvRange span is outside the `Tvb`'s range the creation will cause a runtime error.

`tvbrange:tvb()`

Creates a (sub)Tvb from a TvRange.

`tvbrange:uint()`

Get a Big Endian (network order) unsigned integer from a TvRange. The range must be 1-4 octets long.

Returns

The unsigned integer value.

`tvbrange:le_uint()`

Get a Little Endian unsigned integer from a TvRange. The range must be 1-4 octets long.

Returns

The unsigned integer value.

`tvbrange:uint64()`

Get a Big Endian (network order) unsigned 64 bit integer from a TvRange, as a UInt64 object. The range must be 1-8 octets long.

Returns

The UInt64 object.

`tvbrange:le_uint64()`

Get a Little Endian unsigned 64 bit integer from a TvRange, as a UInt64 object. The range must be 1-8 octets long.

Returns

The UInt64 object.

`tvbrange:int()`

Get a Big Endian (network order) signed integer from a TvRange. The range must be 1-4 octets long.

Returns
The signed integer value

tvrange:le_int()
Get a Little Endian signed integer from a TvbRange. The range must be 1-4 octets long.

Returns
The signed integer value.

tvrange:int64()
Get a Big Endian (network order) signed 64 bit integer from a TvbRange, as an Int64 object. The range must be 1-8 octets long.

Returns
The Int64 object.

tvrange:le_int64()
Get a Little Endian signed 64 bit integer from a TvbRange, as an Int64 object. The range must be 1-8 octets long.

Returns
The Int64 object.

tvrange:float()
Get a Big Endian (network order) floating point number from a TvbRange. The range must be 4 or 8 octets long.

Returns
The floating point value.

tvrange:le_float()
Get a Little Endian floating point number from a TvbRange. The range must be 4 or 8 octets long.

Returns
The floating point value.

tvrange:ipv4()
Get an IPv4 Address from a TvbRange, as an Address object.
Returns
The IPv4 Address object.

tvbrange:le_ipv4()
Get an Little Endian IPv4 Address from a TvbRange, as an Address object.

Returns
The IPv4 Address object.

tvbrange:ipv6()
Get an IPv6 Address from a TvbRange, as an Address object.

Returns
The IPv6 Address object.

tvbrange:ether()
Get an Ethernet Address from a TvbRange, as an Address object.

Returns
The Ethernet Address object.

Errors
- The range must be 6 bytes long

tvbrange:nstime([encoding])
Obtain a time_t structure from a TvbRange, as an NSTime object.

Arguments
encoding (optional)
An optional ENC_* encoding value to use

Returns
The NSTime object and number of bytes used, or nil on failure.

Errors
- The range must be 4 or 8 bytes long
tvbrange:le_nstime()
Obtain a nstime from a TvbRange, as an NSTime object.

Returns
The NSTime object.

Errors
- The range must be 4 or 8 bytes long

tvbrange:string([encoding])
Obtain a string from a TvbRange.

Arguments
encoding (optional)
  The encoding to use. Defaults to ENC_ASCII.

Returns
The string

tvbrange:ustring()
Obtain a Big Endian (network order) UTF-16 encoded string from a TvbRange.

Returns
The string.

tvbrange:le_ustring()
Obtain a Little Endian UTF-16 encoded string from a TvbRange.

Returns
The string.

tvbrange:stringz([encoding])
Obtain a zero terminated string from a TvbRange.

Arguments
encoding (optional)
The encoding to use. Defaults to ENC_ASCII.

Returns

The zero terminated string.

tvrange:ssize([encoding])

Find the size of a zero terminated string from a TvbRange. The size of the string includes the terminating zero.

Since: 1.11.3

Arguments

encoding (optional)

The encoding to use. Defaults to ENC_ASCII.

Returns

Length of the zero terminated string.

tvrange:ustringz()

Obtain a Big Endian (network order) UTF-16 encoded zero terminated string from a TvbRange.

Returns

Two return values: the zero terminated string, and the length.

tvrange:le_ustringz()

Obtain a Little Endian UTF-16 encoded zero terminated string from a TvbRange.

Returns

Two return values: the zero terminated string, and the length.

tvrange:bytes([encoding])

Obtain a ByteArray from a TvbRange.

Starting in 1.11.4, this function also takes an optional encoding argument, which can be set to ENC_STR_HEX to decode a hex-string from the TvbRange into the returned ByteArray. The encoding can be bitwise-or'ed with one or more separator encodings, such as ENC_SEP_COLON, to allow separators to occur between each pair of hex characters.

The return value also now returns the number of bytes used as a second return value.
On failure or error, nil is returned for both return values.

NOTE The encoding type of the hex string should also be set, for example ENC_ASCII or ENC_UTF_8, along with ENC_STR_HEX.

Arguments

encoding (optional)

An optional ENC_* encoding value to use

Returns

The ByteArray object or nil, and number of bytes consumed or nil.

tvbrange:bitfield([position], [length])

Get a bitfield from a TvbRange.

Arguments

position (optional)

The bit offset from the beginning of the TvbRange. Defaults to 0.

length (optional)

The length (in bits) of the field. Defaults to 1.

Returns

The bitfield value

tvbrange:range([offset], [length])

Creates a sub-TvbRange from this TvbRange.

Arguments

offset (optional)

The offset (in octets) from the beginning of the TvbRange. Defaults to 0.

length (optional)

The length (in octets) of the range. Defaults to until the end of the TvbRange.

Returns

The TvbRange
tvbrange:uncompress(name)
Obtain an uncompressed TvbRange from a TvbRange

Arguments
name
The name to be given to the new data-source.

Returns
The TvbRange

tvbrange:len()
Obtain the length of a TvbRange.

tvbrange:offset()
Obtain the offset in a TvbRange.

tvbrange:raw([offset], [length])
Obtain a Lua string of the binary bytes in a TvbRange.
Since: 1.11.3

Arguments
offset (optional)
The position of the first byte (default=0/first).
length (optional)
The length of the segment to get (default=all).

Returns
A Lua string of the binary bytes in the TvbRange.

tvbrange:_eq()
Checks whether the two TvbRange contents are equal.
Since: 1.99.8

tvbrange:_tostring()
Converts the TvbRange into a string. Since the string gets truncated, you should use this only for
debugging purposes or if what you want is to have a truncated string in the format 67:89:AB:...

**Returns**

A Lua hex string of the first 24 binary bytes in the TvbRange.

**Custom file format reading/writing**

The classes/functions defined in this section allow you to create your own custom Lua-based "capture" file reader, or writer, or both.

Since: 1.11.3

**CaptureInfo**

A CaptureInfo object, passed into Lua as an argument by FileHandler callback function `read_open()`, `read()`, `seek_read()`, `seq_read_close()`, and `read_close()`. This object represents capture file data and meta-data (data about the capture file) being read into Wireshark/Tshark.

This object's fields can be written-to by Lua during the read-based function callbacks. In other words, when the Lua plugin's `FileHandler.read_open()` function is invoked, a CaptureInfo object will be passed in as one of the arguments, and its fields should be written to by your Lua code to tell Wireshark about the capture.

Since: 1.11.3

**captureinfo:__tostring()**

Generates a string of debug info for the CaptureInfo

**Returns**

String of debug information.

**captureinfo.encap**

Mode: Retrieve or assign.

The packet encapsulation type for the whole file.

See `wtap_encaps` in `init.lua` for available types. Set to `wtap_encaps.PER_PACKET` if packets can have different types, then later set `FrameInfo.encap` for each packet during `read()`/`seek_read()`.

**captureinfo.time_precision**

Mode: Retrieve or assign.

The precision of the packet timestamps in the file.
See `wtap_file_tsprec` in `init.lua` for available precisions.

`captureinfo.snapshot_length`

Mode: Retrieve or assign.

The maximum packet length that could be recorded.

Setting it to 0 means unknown.

`captureinfo.comment`

Mode: Retrieve or assign.

A string comment for the whole capture file, or nil if there is no `comment`.

`captureinfo.hardware`

Mode: Retrieve or assign.

A string containing the description of the hardware used to create the capture, or nil if there is no `hardware` string.

`captureinfo.os`

Mode: Retrieve or assign.

A string containing the name of the operating system used to create the capture, or nil if there is no `os` string.

`captureinfo.user_app`

Mode: Retrieve or assign.

A string containing the name of the application used to create the capture, or nil if there is no `user_app` string.

`captureinfo.hosts`

Mode: Assign only.

Sets resolved ip-to-hostname information.

The value set must be a Lua table of two key-ed names: `ipv4_addresses` and `ipv6_addresses`. The value of each of these names are themselves array tables, of key-ed tables, such that the inner table has a key `addr` set to the raw 4-byte or 16-byte IP address Lua string and a `name` set to the resolved name.

For example, if the capture file identifies one resolved IPv4 address of 1.2.3.4 to `foo.com`, then you
must set `CaptureInfo.hosts` to a table of:

```plaintext
{ ipv4_addresses = { { addr = \\
    \01\02\03\04\n    , name = "foo.com" } } }
```

Note that either the `ipv4_addresses` or the `ipv6_addresses` table, or both, may be empty or nil.

**captureinfo.private_table**

Mode: Retrieve or assign.

A private Lua value unique to this file.

The `private_table` is a field you set/get with your own Lua table. This is provided so that a Lua script can save per-file reading/writing state, because multiple files can be opened and read at the same time.

For example, if the user issued a reload-file command, or Lua called the `reload()` function, then the current capture file is still open while a new one is being opened, and thus Wireshark will invoke `read_open()` while the previous capture file has not caused `read_close()` to be called; and if the `read_open()` succeeds then `read_close()` will be called right after that for the previous file, rather than the one just opened. Thus the Lua script can use this `private_table` to store a table of values specific to each file, by setting this `private_table` in the `read_open()` function, which it can then later get back inside its `read()`, `seek_read()`, and `read_close()` functions.

**CaptureInfoConst**

A `CaptureInfoConst` object, passed into Lua as an argument to the `FileHandler` callback function `write_open()`.

This object represents capture file data and meta-data (data about the capture file) for the current capture in Wireshark/Tshark.

This object's fields are read-from when used by `write_open` function callback. In other words, when the Lua plugin's FileHandler `write_open` function is invoked, a `CaptureInfoConst` object will be passed in as one of the arguments, and its fields should be read from by your Lua code to get data about the capture that needs to be written.

Since: 1.11.3

**captureinfoconst:_tostring()**

Generates a string of debug info for the `CaptureInfoConst`

**Returns**

String of debug information.
**captureinfoconst.type**

Mode: Retrieve only.

The file type.

**captureinfoconst.snapshot_length**

Mode: Retrieve only.

The maximum packet length that is actually recorded (vs. the original length of any given packet on-the-wire). A value of 0 means the snapshot length is unknown or there is no one such length for the whole file.

**captureinfoconst.encap**

Mode: Retrieve only.

The packet encapsulation type for the whole file.

See `wtap_encaps` in init.lua for available types. It is set to `wtap_encaps.PER_PACKET` if packets can have different types, in which case each Frame identifies its type, in FrameInfo.packet_encap.

**captureinfoconst.comment**

Mode: Retrieve or assign.

A comment for the whole capture file, if the `wtap_presence_flags.COMMENTS` was set in the presence flags; nil if there is no comment.

**captureinfoconst.hardware**

Mode: Retrieve only.

A string containing the description of the hardware used to create the capture, or nil if there is no hardware string.

**captureinfoconst.os**

Mode: Retrieve only.

A string containing the name of the operating system used to create the capture, or nil if there is no os string.

**captureinfoconst.user_app**

Mode: Retrieve only.

A string containing the name of the application used to create the capture, or nil if there is no
**captureinfoconst.hosts**

Mode: Retrieve only.

A ip-to-hostname Lua table of two key-ed names: `ipv4_addresses` and `ipv6_addresses`. The value of each of these names are themselves array tables, of key-ed tables, such that the inner table has a key `addr` set to the raw 4-byte or 16-byte IP address Lua string and a `name` set to the resolved name.

For example, if the current capture has one resolved IPv4 address of 1.2.3.4 to `foo.com`, then getting `CaptureInfoConst.hosts` will get a table of:

```lua
{ ipv4_addresses = { { addr = "\01\02\03\04", name = "foo.com" } }, ipv6_addresses = { } }
```

Note that either the `ipv4_addresses` or the `ipv6_addresses` table, or both, may be empty, however they will not be nil.

**captureinfoconst.private_table**

Mode: Retrieve or assign.

A private Lua value unique to this file.

The `private_table` is a field you set/get with your own Lua table. This is provided so that a Lua script can save per-file reading/writing state, because multiple files can be opened and read at the same time.

For example, if two Lua scripts issue a `Dumper:new_for_current()` call and the current file happens to use your script’s writer, then the Wireshark will invoke `write_open()` while the previous capture file has not had `write_close()` called. Thus the Lua script can use this `private_table` to store a table of values specific to each file, by setting this `private_table` in the `write_open()` function, which it can then later get back inside its `write()`, and `write_close()` functions.

**File**

A `File` object, passed into Lua as an argument by `FileHandler` callback functions (e.g., `read_open`, `read`, `write`, etc.). This behaves similarly to the Lua `io` library's `file` object, returned when calling `io.open()`, **except** in this case you cannot call `file:close()`, `file:open()`, nor `file:setvbuf()`, since Wireshark/tshark manages the opening and closing of files. You also cannot use the ‘io’ library itself on this object, i.e. you cannot do `io.read(file, 4)`. Instead, use this `File` with the object-oriented style calling its methods, i.e. `myfile:read(4)`. (see later example)

The purpose of this object is to hide the internal complexity of how Wireshark handles files, and instead provide a Lua interface that is familiar, by mimicking the `io` library. The reason true/raw `io`
files cannot be used is because Wireshark does many things under the hood, such as compress the file, or write to stdout, or various other things based on configuration/commands.

When a File object is passed in through reading-based callback functions, such as read_open(), read(), and read_close(), then the File object's write() and flush() functions are not usable and will raise an error if used.

When a File object is passed in through writing-based callback functions, such as write_open(), write(), and write_close(), then the File object's read() and lines() functions are not usable and will raise an error if used.

Note: A File object should never be stored/saved beyond the scope of the callback function it is passed in to.

For example:

```lua
function myfilehandler.read_open(file, capture)
    local position = file:seek()

    -- read 24 bytes
    local line = file:read(24)

    -- do stuff

    -- it's not our file type, seek back (unnecessary but just to show it...)
    file:seek("set",position)

    -- return false because it's not our file type
    return false
end
```

Since: 1.11.3

file:read()

Reads from the File, similar to Lua's file:read(). See Lua 5.x ref manual for file:read().

file:seek()

Seeks in the File, similar to Lua's file:seek(). See Lua 5.x ref manual for file:seek().

Returns

The current file cursor position as a number.
file:lines()
Lua iterator function for retrieving ASCII File lines, similar to Lua’s file:lines(). See Lua 5.x ref manual for file:lines.

file:write()
Writes to the File, similar to Lua’s file:write(). See Lua 5.x ref manual for file:write().

file:__tostring()
Generates a string of debug info for the File object

Returns
String of debug information.

file.compressed
Mode: Retrieve only.
Whether the File is compressed or not.

See wtap_encaps in init.lua for available types. Set to wtap_encaps.PER_PACKET if packets can have different types, then later set FrameInfo.encap for each packet during read()/seek_read().

FileHandler
A FileHandler object, created by a call to FileHandler.new(arg1, arg2, ...). The FileHandler object lets you create a file-format reader, or writer, or both, by setting your own read_open/read or write_open/write functions.

Since: 1.11.3

FileHandler.new(name, shortname, description, type)
Creates a new FileHandler

Arguments

name
The name of the file type, for display purposes only. E.g., "Wireshark - pcapng"

shortname
The file type short name, used as a shortcut in various places. E.g., "pcapng". Note: The name cannot already be in use.
description

Descriptive text about this file format, for display purposes only

type

The type of FileHandler, "r"/"w"/"rw" for reader/writer/both, include "m" for magic, "s" for strong heuristic

Returns

The newly created FileHandler object

filehandler:__tostring()

Generates a string of debug info for the FileHandler

Returns

String of debug information.

filehandler.read_open

Mode: Assign only.

The Lua function to be called when Wireshark opens a file for reading.

When later called by Wireshark, the Lua function will be given:

1. A File object
2. A CaptureInfo object

The purpose of the Lua function set to this read_open field is to check if the file Wireshark is opening is of its type, for example by checking for magic numbers or trying to parse records in the file, etc. The more can be verified the better, because Wireshark tries all file readers until it finds one that accepts the file, so accepting an incorrect file prevents other file readers from reading their files.

The called Lua function should return true if the file is its type (it accepts it), false if not. The Lua function must also set the File offset position (using file:seek()) to where it wants it to be for its first read() call.

filehandler.read

Mode: Assign only.

The Lua function to be called when Wireshark wants to read a packet from the file.

When later called by Wireshark, the Lua function will be given:

1. A File object
2. A `CaptureInfo` object
3. A `FrameInfo` object

The purpose of the Lua function set to this `read` field is to read the next packet from the file, and setting the parsed/read packet into the frame buffer using `FrameInfo.data = foo` or `FrameInfo:read_data(file, frame.captured_length)`.

The called Lua function should return the file offset/position number where the packet begins, or false if it hit an error. The file offset will be saved by Wireshark and passed into the set `seek_read()` Lua function later.

**filehandler.seek_read**

Mode: Assign only.

The Lua function to be called when Wireshark wants to read a packet from the file at the given offset.

When later called by Wireshark, the Lua function will be given:

1. A `File` object
2. A `CaptureInfo` object
3. A `FrameInfo` object
4. The file offset number previously set by the `read()` function call

The called Lua function should return true if the read was successful, or false if it hit an error. Since 2.4.0, a number is also acceptable to signal success, this allows for reuse of `FileHandler:read`:

```lua
local function fh_read(file, capture, frame) ... end
myfilehandler.read = fh_read

function myfilehandler.seek_read(file, capture, frame, offset)
    if not file:seek("set", offset) then
        -- Seeking failed, return failure
        return false
    end

    -- Now try to read one frame
    return fh_read(file, capture, frame)
end
```

**filehandler.read_close**

Mode: Assign only.
The Lua function to be called when Wireshark wants to close the read file completely.

When later called by Wireshark, the Lua function will be given:

1. A File object
2. A CaptureInfo object

It is not necessary to set this field to a Lua function - FileHandler can be registered without doing so - it is available in case there is memory/state to clear in your script when the file is closed.

**filehandler.seq_read_close**

Mode: Assign only.

The Lua function to be called when Wireshark wants to close the sequentially-read file.

When later called by Wireshark, the Lua function will be given:

1. A File object
2. A CaptureInfo object

It is not necessary to set this field to a Lua function - FileHandler can be registered without doing so - it is available in case there is memory/state to clear in your script when the file is closed for the sequential reading portion. After this point, there will be no more calls to read(), only seek_read().

**filehandler.can_write_encap**

Mode: Assign only.

The Lua function to be called when Wireshark wants to write a file, by checking if this file writer can handle the wtap packet encapsulation(s).

When later called by Wireshark, the Lua function will be given a Lua number, which matches one of the encapsulations in the Lua wtap_encaps table. This might be the wtap_encap.PER_PACKET number, meaning the capture contains multiple encapsulation types, and the file reader should only return true if it can handle multiple encap types in one file. The function will then be called again, once for each encap type in the file, to make sure it can write each one.

If the Lua file writer can write the given type of encapsulation into a file, then it returns the boolean true, else false.

**filehandler.write_open**

Mode: Assign only.

The Lua function to be called when Wireshark opens a file for writing.

When later called by Wireshark, the Lua function will be given:
1. A File object
2. A CaptureInfoConst object

The purpose of the Lua function set to this write_open field is similar to the read_open callback function: to initialize things necessary for writing the capture to a file. For example, if the output file format has a file header, then the file header should be written within this write_open function.

The called Lua function should return true on success, or false if it hit an error.

Also make sure to set the FileHandler.write (and potentially FileHandler.write_finish) functions before returning true from this function.

**filehandler.write**

Mode: Assign only.

The Lua function to be called when Wireshark wants to write a packet to the file.

When later called by Wireshark, the Lua function will be given:

1. A File object
2. A CaptureInfoConst object
3. A FrameInfoConst object of the current frame/packet to be written

The purpose of the Lua function set to this write field is to write the next packet to the file.

The called Lua function should return true on success, or false if it hit an error.

**filehandler.write_finish**

Mode: Assign only.

The Lua function to be called when Wireshark wants to close the written file.

When later called by Wireshark, the Lua function will be given:

1. A File object
2. A CaptureInfoConst object

It is not necessary to set this field to a Lua function - FileHandler can be registered without doing so - it is available in case there is memory/state to clear in your script when the file is closed.

**filehandler.type**

Mode: Retrieve only.

The internal file type. This is automatically set with a new number when the FileHandler is
registered.

**filehandler.extensions**

Mode: Retrieve or assign.

One or more semicolon-separated file extensions that this file type usually uses.

For readers using heuristics to determine file type, Wireshark will try the readers of the file's extension first, before trying other readers. But ultimately Wireshark tries all file readers for any file extension, until it finds one that accepts the file.

(Since 2.6) For writers, the first extension is used to suggest the default file extension.

**filehandler.writing_must_seek**

Mode: Retrieve or assign.

True if the ability to seek is required when writing this file format, else false.

This will be checked by Wireshark when writing out to compressed file formats, because seeking is not possible with compressed files. Usually a file writer only needs to be able to seek if it needs to go back in the file to change something, such as a block or file length value earlier in the file.

**filehandler.writes_name_resolution**

Mode: Retrieve or assign.

True if the file format supports name resolution records, else false.

**filehandler.supported_comment_types**

Mode: Retrieve or assign.

Set to the bit-wise OR'ed number representing the type of comments the file writer supports writing, based on the numbers in the `wtap_comments` table.

**FrameInfo**

A FrameInfo object, passed into Lua as an argument by FileHandler callback functions (e.g., `read`, `seek_read`, etc.).

This object represents frame data and meta-data (data about the frame/packet) for a given read/seek_read/write's frame.

This object's fields are written-to/set when used by read function callbacks, and read-from/get when used by file write function callbacks. In other words, when the Lua plugin's FileHandler read/seek_read/etc. functions are invoked, a FrameInfo object will be passed in as one of the arguments,
and its fields should be written-to/set based on the frame information read from the file; whereas when the Lua plugin's FileHandler.write() function is invoked, the FrameInfo object passed in should have its fields read-from/get, to write that frame information to the file.

Since: 1.11.3

frameinfo:_tostring()

Generates a string of debug info for the FrameInfo

**Returns**

String of debug information.

frameinfo:read_data(file, length)

Tells Wireshark to read directly from given file into frame data buffer, for length bytes. Returns true if succeeded, else false.

**Arguments**

file

The File object userdata, provided by Wireshark previously in a reading-based callback.

length

The number of bytes to read from the file at the current cursor position.

**Returns**

True if succeeded, else returns false along with the error number and string error description.

A Lua string of the frame buffer's data.

frameinfo.time

Mode: Retrieve or assign.

The packet timestamp as an NSTime object.

Note: Set the FileHandler.time_precision to the appropriate wtap_file_tsprec value as well.

frameinfo.data

Mode: Retrieve or assign.

The data buffer containing the packet.

NOTE This cannot be cleared once set.
frameinfo.rec_type
Mode: Retrieve or assign.
The record type of the packet frame
See `wtap_rec_types` in `init.lua` for values.

frameinfo.flags
Mode: Retrieve or assign.
The presence flags of the packet frame.
See `wtap_presence_flags` in `init.lua` for bit values.

frameinfo.captured_length
Mode: Retrieve or assign.
The captured packet length, and thus the length of the buffer passed to the FrameInfo.data field.

frameinfo.original_length
Mode: Retrieve or assign.
The on-the-wire packet length, which may be longer than the captured_length.

frameinfo.encap
Mode: Retrieve or assign.
The packet encapsulation type for the frame/packet, if the file supports per-packet types. See `wtap_encaps` in `init.lua` for possible packet encapsulation types to use as the value for this field.

frameinfo.comment
Mode: Retrieve or assign.
A string comment for the packet, if the `wtap_presence_flags.COMMENTS` was set in the presence flags; nil if there is no comment.

FrameInfoConst
A constant FrameInfo object, passed into Lua as an argument by the FileHandler write callback function. This has similar attributes/properties as FrameInfo, but the fields can only be read from, not written to.

Since: 1.11.3
frameinfoconst:__tostring()  
Generates a string of debug info for the FrameInfo

Returns
String of debug information.

frameinfoconst:write_data(file, [length])  
Tells Wireshark to write directly to given file from the frame data buffer, for length bytes. Returns true if succeeded, else false.

Arguments
file  
The File object userdata, provided by Wireshark previously in a writing-based callback.

length (optional)  
The number of bytes to write to the file at the current cursor position, or all if not supplied.

Returns
True if succeeded, else returns false along with the error number and string error description.

frameinfoconst.time  
Mode: Retrieve only.

The packet timestamp as an NSTime object.

frameinfoconst.data  
Mode: Retrieve only.

The data buffer containing the packet.

frameinfoconst.rec_type  
Mode: Retrieve only.

The record type of the packet frame - see wtap_presence_flags in init.lua for values.

frameinfoconst.flags  
Mode: Retrieve only.

The presence flags of the packet frame - see wtap_presence_flags in init.lua for bits.
frameinfoconst.captured_length

Mode: Retrieve only.

The captured packet length, and thus the length of the buffer in the FrameInfoConst.data field.

frameinfoconst.original_length

Mode: Retrieve only.

The on-the-wire packet length, which may be longer than the captured_length.

frameinfoconst.encap

Mode: Retrieve only.

The packet encapsulation type, if the file supports per-packet types.

See wtap_encaps in init.lua for possible packet encapsulation types to use as the value for this field.

frameinfoconst.comment

Mode: Retrieve only.

A comment for the packet; nil if there is none.

Global Functions

register_filehandler(filehandler)

Register the FileHandler into Wireshark/tshark, so they can read/write this new format. All functions and settings must be complete before calling this registration function. This function cannot be called inside the reading/writing callback functions.

Arguments

filehandler

The FileHandler object to be registered

Returns

the new type number for this file reader/write

deregister_filehandler(filehandler)

Deregister the FileHandler from Wireshark/tshark, so it no longer gets used for reading/writing/display. This function cannot be called inside the reading/writing callback functions.
Arguments

**filehandler**

The FileHandler object to be deregistered

**Directory handling functions**

**Dir**

A Directory object, as well as associated functions.

**Dir.make(name)**

Creates a directory.

The created directory is set for permission mode 0755 (octal), meaning it is read+write+execute by owner, but only read+execute by group and others.

IF the directory was created successfully, a boolean **true** is returned. If the directory cannot be made because it already exists, **false** is returned. If the directory cannot be made because an error occurred, **nil** is returned.

Since: 1.11.3

**Arguments**

**name**

The name of the directory, possibly including path.

**Returns**

Boolean **true** on success, **false** if already exists, **nil** on error.

**Dir.exists(name)**

Returns true if the given directory name exists.

If the directory exists, a boolean **true** is returned. If the path is a file instead, **false** is returned. If the path does not exist or an error occurred, **nil** is returned.

Since: 1.11.3

**Arguments**

**name**

The name of the directory, possibly including path.
Returns

Boolean `true` if the directory exists, `false` if it's a file, `nil` on error/not-exist.

Dir.remove(name)

Removes an empty directory.

If the directory was removed successfully, a boolean `true` is returned. If the directory cannot be removed because it does not exist, `false` is returned. If the directory cannot be removed because an error occurred, `nil` is returned.

This function only removes empty directories. To remove a directory regardless, use `Dir.remove_all()`.

Since: 1.11.3

Arguments

name

The name of the directory, possibly including path.

Returns

Boolean `true` on success, `false` if does not exist, `nil` on error.

Dir.remove_all(name)

Removes an empty or non-empty directory.

If the directory was removed successfully, a boolean `true` is returned. If the directory cannot be removed because it does not exist, `false` is returned. If the directory cannot be removed because an error occurred, `nil` is returned.

Since: 1.11.3

Arguments

name

The name of the directory, possibly including path.

Returns

Boolean `true` on success, `false` if does not exist, `nil` on error.

Dir.open(pathname, [extension])

Opens a directory and returns a `Dir` object representing the files in the directory.
for filename in Dir.open(path) do ... end

Arguments

pathname
  The pathname of the directory.

extension (optional)
  If given, only files with this extension will be returned.

Returns
  the Dir object.

Dir.personal_config_path([filename])

Gets the personal configuration directory path, with filename if supplied.

Since: 1.11.3

Arguments

filename (optional)
  A filename.

Returns
  The full pathname for a file in the personal configuration directory.

Dir.global_config_path([filename])

Gets the global configuration directory path, with filename if supplied.

Since: 1.11.3

Arguments

filename (optional)
  A filename

Returns
  The full pathname for a file in wireshark's configuration directory.
**Dir.personal_plugins_path()**

Gets the personal plugins directory path.

Since: 1.11.3

**Returns**

The pathname for the personal plugins directory.

**Dir.global_plugins_path()**

Gets the global plugins directory path.

Since: 1.11.3

**Returns**

The pathname for the global plugins directory.

**dir:__call()**

At every invocation will return one file (nil when done).

**dir:close()**

Closes the directory.

**Utility Functions**

**Global Functions**

**get_version()**

Gets a string of the Wireshark version.

**Returns**

version string

**set_plugin_info(table)**

Set a Lua table with meta-data about the plugin, such as version.

The passed-in Lua table entries need to be keyed/indexed by the following:

- "version" with a string value identifying the plugin version (required)
- "description" with a string value describing the plugin (optional)
• "author" with a string value of the author's name(s) (optional)
• "repository" with a string value of a URL to a repository (optional)

Not all of the above key entries need to be in the table. The 'version' entry is required, however. The others are not currently used for anything, but might be in the future and thus using them might be useful. Table entries keyed by other strings are ignored, and do not cause an error.

Example:

```lua
local my_info = {
    version = "1.0.1",
    author = "Jane Doe",
    repository = "https://github.com/octocat/Spoon-Knife"
}

set_plugin_info(my_info)
```

Since: 1.99.8

Arguments

`table`

The Lua table of information.

`format_date(timestamp)`

Formats an absolute timestamp into a human readable date.

Arguments

`timestamp`

A timestamp value to convert.

Returns

A string with the formatted date

`format_time(timestamp)`

Formats a relative timestamp in a human readable form.

Arguments

`timestamp`

A timestamp value to convert.
Returns
A string with the formatted time

\texttt{report\_failure(text)}
Reports a failure to the user.

**Arguments**

\textbf{text}
Message text to report.

\texttt{loadfile(filename)}
Lua’s \texttt{loadfile()} has been modified so that if a file does not exist in the current directory it will look for it in Wireshark’s user and system directories.

**Arguments**

\textbf{filename}
Name of the file to be loaded.

\texttt{dofile(filename)}
Lua’s \texttt{dofile()} has been modified so that if a file does not exist in the current directory it will look for it in Wireshark’s user and system directories.

**Arguments**

\textbf{filename}
Name of the file to be run.

\texttt{register\_stat\_cmd\_arg(argument, [action])}
Register a function to handle a \texttt{-z} option

**Arguments**

\textbf{argument}
Argument

\textbf{action (optional)}
Action
Handling 64-bit Integers

Lua uses one single number representation which can be chosen at compile time and since it is often set to IEEE 754 double precision floating point, one cannot store a 64 bit integer with full precision.

For details, see https://wiki.wireshark.org/LuaAPI/Int64.

Int64

Int64 represents a 64 bit signed integer.

For details, see https://wiki.wireshark.org/LuaAPI/Int64.

Int64.decode(string, [endian])

Decodes an 8-byte Lua string, using given endianness, into a new Int64 object.

Since: 1.11.3

Arguments

string
  The Lua string containing a binary 64-bit integer.

endian (optional)
  If set to true then little-endian is used, if false then big-endian; if missing/nil, native host endian.

Returns

The Int64 object created, or nil on failure.

Int64.new([value], [highvalue])

Creates a Int64 Object.

Since: 1.11.3

Arguments

value (optional)
  A number,(UInt64, Int64, or string of ASCII digits to assign the value of the new Int64 (default=0).

highvalue (optional)
  If this is a number and the first argument was a number, then the first will be treated as a lower 32-bits, and this is the high-order 32 bit number.
Returns
The new `Int64` object.

**Int64.max()**
Gets the max possible value.
Since: 1.11.3

Returns
The new `Int64` object of the max value.

**Int64.min()**
Gets the min possible value.
Since: 1.11.3

Returns
The new `Int64` object of the min value.

**Int64.fromhex(hex)**
Creates an `Int64` object from the given hex string.
Since: 1.11.3

Arguments
hex
The hex-ascii Lua string.

Returns
The new `Int64` object.

**int64:encode([endian])**
Encodes the `Int64` number into an 8-byte Lua string, using given endianness.
Since: 1.11.3

Arguments
endian (optional)
If set to true then little-endian is used, if false then big-endian; if missing/nil, native host endian.
**Returns**
The Lua string.

**int64:__call()**
Creates a Int64 Object.

Since: 1.11.3

**Returns**
The new Int64 object.

**int64:tonumber()**
Returns a Lua number of the Int64 value - this may lose precision.

Since: 1.11.3

**Returns**
The Lua number.

**int64:tohex(numbytes)**
Returns a hex string of the Int64 value.

Since: 1.11.3

**Arguments**

**numbytes (optional)**

The number of hex-chars/nibbles to generate, negative means uppercase (default=16).

**Returns**
The string hex.

**int64:higher()**
Returns a Lua number of the higher 32-bits of the Int64 value. (negative Int64 will return a negative Lua number).

Since: 1.11.3

**Returns**
The Lua number.
**int64:lower()**

Returns a Lua number of the lower 32-bits of the Int64 value. (always positive).

Since: 1.11.3

**Returns**

The Lua number.

**int64:__tostring()**

Converts the Int64 into a string of decimal digits.

**Returns**

The Lua string.

**int64:__unm()**

Returns the negative of the Int64, in a new Int64.

Since: 1.11.3

**Returns**

The new Int64.

**int64:__add()**

Adds two Int64 together and returns a new one (this may wrap the value).

Since: 1.11.3

**int64:__sub()**

Subtracts two Int64 and returns a new one (this may wrap the value).

Since: 1.11.3

**int64:__mul()**

Multiplies two Int64 and returns a new one (this may truncate the value).

Since: 1.11.3

**int64:__div()**

Divides two Int64 and returns a new one (integer divide, no remainder). Trying to divide by zero
results in a Lua error.
Since: 1.11.3

**Returns**
The `Int64` object.

`int64:__mod()`
Divides two `Int64` and returns a new one of the remainder. Trying to modulo by zero results in a Lua error.
Since: 1.11.3

**Returns**
The `Int64` object.

`int64:__pow()`
The first `Int64` is taken to the power of the second `Int64`, returning a new one (this may truncate the value).
Since: 1.11.3

**Returns**
The `Int64` object.

`int64:__eq()`
Returns true if both `Int64` are equal.
Since: 1.11.3

`int64:__lt()`
Returns true if first `Int64` < second.
Since: 1.11.3

`int64:__le()`
Returns true if first `Int64` ≤ second.
Since: 1.11.3
int64:bnot()

Returns a Int64 of the bitwise 'not' operation.

Since: 1.11.3

Returns

The Int64 object.

int64:band()

Returns a Int64 of the bitwise 'and' operation, with the given number/Int64/UIInt64. Note that multiple arguments are allowed.

Since: 1.11.3

Returns

The Int64 object.

int64:bor()

Returns a Int64 of the bitwise 'or' operation, with the given number/Int64/UIInt64. Note that multiple arguments are allowed.

Since: 1.11.3

Returns

The Int64 object.

int64:bxor()

Returns a Int64 of the bitwise 'xor' operation, with the given number/Int64/UIInt64. Note that multiple arguments are allowed.

Since: 1.11.3

Returns

The Int64 object.

int64:lshift(numbits)

Returns a Int64 of the bitwise logical left-shift operation, by the given number of bits.

Since: 1.11.3
Arguments
numbits
   The number of bits to left-shift by.

Returns
The Int64 object.

int64:rshift(numbits)
Returns a Int64 of the bitwise logical right-shift operation, by the given number of bits.
Since: 1.11.3

Arguments
numbits
   The number of bits to right-shift by.

Returns
The Int64 object.

int64:arshift(numbits)
Returns a Int64 of the bitwise arithmetic right-shift operation, by the given number of bits.
Since: 1.11.3

Arguments
numbits
   The number of bits to right-shift by.

Returns
The Int64 object.

int64:rol(numbits)
Returns a Int64 of the bitwise left rotation operation, by the given number of bits (up to 63).
Since: 1.11.3

Arguments
numbits
The number of bits to roll left by.

**Returns**

The [Int64](https://wiki.wireshark.org/LuaAPI/Int64) object.

**int64:ror(numbits)**

Returns a Int64 of the bitwise right rotation operation, by the given number of bits (up to 63).

Since: 1.11.3

**Arguments**

**numbits**

The number of bits to roll right by.

**Returns**

The Int64 object.

**int64:bswap()**

Returns a Int64 of the bytes swapped. This can be used to convert little-endian 64-bit numbers to big-endian 64 bit numbers or vice versa.

Since: 1.11.3

**Returns**

The Int64 object.

**UInt64**

**UInt64** represents a 64 bit unsigned integer, similar to Int64.

For details, see: [https://wiki.wireshark.org/LuaAPI/Int64](https://wiki.wireshark.org/LuaAPI/Int64).

**UInt64.decode(string, [endian])**

Decodes an 8-byte Lua binary string, using given endianness, into a new [UInt64](https://wiki.wireshark.org/LuaAPI/UInt64) object.

Since: 1.11.3

**Arguments**

**string**

The Lua string containing a binary 64-bit integer.
endian (optional)

If set to true then little-endian is used, if false then big-endian; if missing/nil, native host endian.

Returns

The(UInt64) object created, or nil on failure.

(UInt64.new([value], [highvalue]))

Creates a(UInt64) Object.

Since: 1.11.3

Arguments

value (optional)

A number, UInt64, Int64, or string of digits to assign the value of the new(UInt64) (default=0).

highvalue (optional)

If this is a number and the first argument was a number, then the first will be treated as a lower 32-bits, and this is the high-order 32-bit number.

Returns

The new(UInt64) object.

(UInt64.max())

Gets the max possible value.

Since: 1.11.3

Returns

The max value.

(UInt64.min())

Gets the min possible value (i.e., 0).

Since: 1.11.3

Returns

The min value.
**UInt64.fromhex(hex)**

Creates a `UInt64` object from the given hex string.

Since: 1.11.3

**Arguments**

hex

The hex-ascii Lua string.

**Returns**

The new `UInt64` object.

**uint64:encode([endian])**

Encodes the `UInt64` number into an 8-byte Lua binary string, using given endianness.

Since: 1.11.3

**Arguments**

endian (optional)

If set to true then little-endian is used, if false then big-endian; if missing/nil, native host endian.

**Returns**

The Lua binary string.

**uint64:_call()**

Creates a `UInt64` Object.

Since: 1.11.3

**Returns**

The new `UInt64` object.

**uint64:tonumber()**

Returns a Lua number of the `UInt64` value - this may lose precision.

Since: 1.11.3

**Returns**

The Lua number.
uint64:_tostring()

Converts the UInt64 into a string.

**Returns**
The Lua string.

uint64:tohex([numbytes])

Returns a hex string of the UInt64 value.

Since: 1.11.3

**Arguments**

numbytes (optional)
The number of hex-chars/nibbles to generate, negative means uppercase (default=16).

**Returns**
The string hex.

uint64:higher()

Returns a Lua number of the higher 32-bits of the UInt64 value.

**Returns**
The Lua number.

uint64:lower()

Returns a Lua number of the lower 32-bits of the UInt64 value.

**Returns**
The Lua number.

uint64:_unm()

Returns the UInt64, in a new UInt64, since unsigned integers can’t be negated.

Since: 1.11.3

**Returns**
The UInt64 object.
**uint64:__add()**

Adds two `UInt64` together and returns a new one (this may wrap the value).

Since: 1.11.3

**uint64:__sub()**

Subtracts two `UInt64` and returns a new one (this may wrap the value).

Since: 1.11.3

**uint64:__mul()**

Multiplies two `UInt64` and returns a new one (this may truncate the value).

Since: 1.11.3

**uint64:__div()**

Divides two `UInt64` and returns a new one (integer divide, no remainder). Trying to divide by zero results in a Lua error.

Since: 1.11.3

**Returns**

The `UInt64` result.

**uint64:__mod()**

Divides two `UInt64` and returns a new one of the remainder. Trying to modulo by zero results in a Lua error.

Since: 1.11.3

**Returns**

The `UInt64` result.

**uint64:__pow()**

The first `UInt64` is taken to the power of the second `UInt64`/number, returning a new one (this may truncate the value).

Since: 1.11.3

**Returns**
The **UInt64** object.

**uint64:__eq()**

Returns true if both **UInt64** are equal.

Since: 1.11.3

**uint64:__lt()**

Returns true if first **UInt64** < second.

Since: 1.11.3

**uint64:__le()**

Returns true if first **UInt64** ⇐ second.

Since: 1.11.3

**uint64:bnot()**

Returns a **UInt64** of the bitwise 'not' operation.

Since: 1.11.3

**Returns**

The **UInt64** object.

**uint64:band()**

Returns a **UInt64** of the bitwise 'and' operation, with the given number/Int64/UInt64. Note that multiple arguments are allowed.

Since: 1.11.3

**Returns**

The **UInt64** object.

**uint64:bor()**

Returns a **UInt64** of the bitwise 'or' operation, with the given number/Int64/UInt64. Note that multiple arguments are allowed.

Since: 1.11.3

**Returns**
The `UInt64` object.

`uint64:bxor()`

Returns a `UInt64` of the bitwise ‘xor’ operation, with the given number/`Int64/` `UInt64`. Note that multiple arguments are allowed.

Since: 1.11.3

**Returns**

The `UInt64` object.

`uint64:lshift(numbits)`

Returns a `UInt64` of the bitwise logical left-shift operation, by the given number of bits.

Since: 1.11.3

**Arguments**

`numbits`  
The number of bits to left-shift by.

**Returns**

The `UInt64` object.

`uint64:rshift(numbits)`

Returns a `UInt64` of the bitwise logical right-shift operation, by the given number of bits.

Since: 1.11.3

**Arguments**

`numbits`  
The number of bits to right-shift by.

**Returns**

The `UInt64` object.

`uint64:arshift(numbits)`

Returns a `UInt64` of the bitwise arithmetic right-shift operation, by the given number of bits.

Since: 1.11.3
Arguments

numbits

The number of bits to right-shift by.

Returns

The UInt64 object.

uint64:rol(numbits)

Returns a UInt64 of the bitwise left rotation operation, by the given number of bits (up to 63).

Since: 1.11.3

Arguments

numbits

The number of bits to roll left by.

Returns

The UInt64 object.

uint64:ror(numbits)

Returns a UInt64 of the bitwise right rotation operation, by the given number of bits (up to 63).

Since: 1.11.3

Arguments

numbits

The number of bits to roll right by.

Returns

The UInt64 object.

uint64:bswap()

Returns a UInt64 of the bytes swapped. This can be used to convert little-endian 64-bit numbers to big-endian 64 bit numbers or vice versa.

Since: 1.11.3

Returns
The **UInt64** object.

## Binary encode/decode support

The Struct class offers basic facilities to convert Lua values to and from C-style structs in binary Lua strings. This is based on Roberto Ierusalimschy's Lua struct library found in [http://www.inf.puc-rio.br/~roberto/struct/](http://www.inf.puc-rio.br/~roberto/struct/), with some minor modifications as follows:

- Added support for **Int64/UInt64** being packed/unpacked, using 'e'/E'.
- Can handle 'long long' integers (i8 / I8); though they're converted to doubles.
- Can insert/specify padding anywhere in a struct. ('X' eg. when a string is following a union).
- Can report current offset in both **pack** and **unpack** (‘=’).
- Can mask out return values when you only want to calculate sizes or unmarshal pascal-style strings using (‘ & ’).

All but the first of those changes are based on an email from Flemming Madsen, on the lua-users mailing list, which can be found [here](http://www.inf.puc-rio.br/~roberto/struct/).

The main functions are `Struct.pack`, which packs multiple Lua values into a struct-like Lua binary string; and `Struct.unpack`, which unpacks multiple Lua values from a given struct-like Lua binary string. There are some additional helper functions available as well.

All functions in the Struct library are called as static member functions, not object methods, so they are invoked as "Struct.pack(...)" instead of "object:pack(...)".

The fist argument to several of the `Struct` functions is a format string, which describes the layout of the structure. The format string is a sequence of conversion elements, which respect the current endianness and the current alignment requirements. Initially, the current endianness is the machine's native endianness and the current alignment requirement is 1 (meaning no alignment at all). You can change these settings with appropriate directives in the format string.

The supported elements in the format string are as follows:

- `' ' (empty space) ignored.
- `!n` flag to set the current alignment requirement to 'n' (necessarily a power of 2); an absent 'n' means the machine's native alignment.
- `>' flag to set mode to big endian (i.e., network-order).
- `<` flag to set mode to little endian.
- 'x' a padding zero byte with no corresponding Lua value.
- 'b' a signed char.
- 'B' an unsigned char.
- 'h' a signed short (native size).
• `H` an unsigned short (native size).
• `I` a signed long (native size).
• `L` an unsigned long (native size).
• `T` a size_t (native size).
• `in` a signed integer with 'n' bytes. An absent 'n' means the native size of an int.
• `In` like `in` but unsigned.
• `e` signed 8-byte Integer (64-bits, long long), to/from a Int64 object.
• `E` unsigned 8-byte Integer (64-bits, long long), to/from a UInt64 object.
• `f` a float (native size).
• `d` a double (native size).
• `s` a zero-terminated string.
• `cn` a sequence of exactly 'n' chars corresponding to a single Lua string. An absent 'n' means 1. When packing, the given string must have at least 'n' characters (extra characters are discarded).
• `cn` this is like `cn`, except that the 'n' is given by other means: When packing, 'n' is the length of the given string; when unpacking, 'n' is the value of the previous unpacked value (which must be a number). In that case, this previous value is not returned.
• `xn` pad to 'n' number of bytes, default 1.
• `Xn` pad to 'n' alignment, default MAXALIGN.
• `(` to stop assigning items, and ``)` start assigning (padding when packing).
• `=` to return the current position / offset.

Using `i`, `I`, `h`, `H`, `l`, `l`, `f`, and `T` is strongly discouraged, as those sizes are system-dependent. Use the explicitly sized variants instead, such as `i4` or `E`.

Unpacking of `i/I` is done to a Lua number, a double-precision floating point, so unpacking a 64-bit field (`i8/I8`) will lose precision. Use `e/E` to unpack into a Wireshark Int64/UInt64 object instead.

Since: 1.11.3

**Struct**

**Struct.pack(format, value)**

Returns a string containing the values arg1, arg2, etc. packed/encoded according to the format string.

**Arguments**
format
   The format string

value
   One or more Lua value(s) to encode, based on the given format.

Returns
The packed binary Lua string, plus any positions due to ‘=’ being used in format.

Struct.unpack(format, struct, [begin])
Unpacks/decodes multiple Lua values from a given struct-like binary Lua string. The number of returned values depends on the format given, plus an additional value of the position where it stopped reading is returned.

Arguments
format
   The format string

struct
   The binary Lua string to unpack

begin (optional)
   The position to begin reading from (default=1)

Returns
One or more values based on format, plus the position it stopped unpacking.

Struct.size(format)
Returns the length of a binary string that would be consumed/handled by the given format string.

Arguments
format
   The format string

Returns
The size number

Struct.values(format)
Returns the number of Lua values contained in the given format string. This will be the number of
returned values from a call to Struct.unpack() not including the extra return value of offset position. (i.e., Struct.values() does not count that extra return value) This will also be the number of arguments Struct.pack() expects, not including the format string argument.

Arguments

format

The format string

Returns

The number of values

Struct.tohex(bytestring, [lowercase], [separator])

Converts the passed-in binary string to a hex-ascii string.

Arguments

bytestring

A Lua string consisting of binary bytes

lowercase (optional)

True to use lower-case hex characters (default=false).

separator (optional)

A string separator to insert between hex bytes (default=nil).

Returns

The Lua hex-ascii string

Struct.fromhex(hexbytes, [separator])

Converts the passed-in hex-ascii string to a binary string.

Arguments

hexbytes

A string consisting of hexadecimal bytes like "00 B1 A2" or "1a2b3c4d"

separator (optional)

A string separator between hex bytes/words (default none).

Returns

The Lua binary string
GLib Regular Expressions

Lua has its own native pattern syntax in the string library, but sometimes a real regex engine is more useful. Wireshark comes with GLib's Regex implementation, which itself is based on Perl Compatible Regular Expressions (PCRE). This engine is exposed into Wireshark's Lua engine through the well-known Lrexlib library, following the same syntax and semantics as the Lrexlib PCRE implementation, with a few differences as follows:

- There is no support for using custom locale/chartables
- `dfa_exec()` doesn't take `ovesize` nor `wscount` arguments
- `dfa_exec()` returns boolean true for partial match, without subcapture info
- Named subgroups do not return name-keyed entries in the return table (i.e., in `match/tfind/exec`)
- The `flags()` function still works, returning all flags, but two new functions `compile_flags()` and `match_flags()` return just their respective flags, since GLib has a different and smaller set of such flags, for regex compile vs. match functions
- Using some assertions and POSIX character classes against strings with non-ASCII characters might match high-order characters, because glib always sets PCRE_UCP even if G_REGEX_RAW is set. For example, [[:alpha:]] matches certain non-ASCII bytes. The following assertions have this issue: \b, \B, \s, \S, \w, \W. The following character classes have this issue: [:alpha:], [:alnum:], [:lower:], [:upper:], [:space:], [:word:], and [:graph:].
- The compile flag G_REGEX_RAW is always set/used, even if you didn't specify it. This is because GLib runs PCRE in UTF-8 mode by default, whereas Lua strings are not UTF-aware.

Since: 1.11.3

This page is based on the full documentation for Lrexlib at https://rrthomas.github.io/lrexlib/manual.html

The GLib Regular expression syntax (which is essentially PCRE syntax) can be found at https://developer.gnome.org/glib/2.38/glib-regex-syntax.html

GRegex

GLib Regular Expressions based on PCRE.

Since: 1.11.3

Notes

All functions that take a regular expression pattern as an argument will generate an error if that pattern is found invalid by the regex library.

All functions that take a string-type regex argument accept a compiled regex too. In this case, the
The capture flag argument \textit{cf} may also be supplied as a string, whose characters stand for compilation flags. Combinations of the following characters (case sensitive) are supported:

- \textit{i} = G\textunderscore{}REGEX\_CASELESS - Letters in the pattern match both upper- and lowercase letters. This option can be changed within a pattern by a “(?i)” option setting.
- \textit{m} = G\textunderscore{}REGEX\_MULTILINE - By default, GRegex treats the strings as consisting of a single line of characters (even if it actually contains newlines). The “start of line” metacharacter (“^”) matches only at the start of the string, while the “end of line” metacharacter (“$”) matches only at the end of the string, or before a terminating newline (unless G\textunderscore{}REGEX\_DOLLAR\_ENDONLY is set). When G\textunderscore{}REGEX\_MULTILINE is set, the “start of line” and “end of line” constructs match immediately following or immediately before any newline in the string, respectively, as well as at the very start and end. This can be changed within a pattern by a “(?m)” option setting.
- \textit{s} = G\textunderscore{}REGEX\_DOTALL - A dot metacharacter (“.”) in the pattern matches all characters, including newlines. Without it, newlines are excluded. This option can be changed within a pattern by a (“?s”) option setting.
- \textit{x} = G\textunderscore{}REGEX\_EXTENDED - Whitespace data characters in the pattern are totally ignored except when escaped or inside a character class. Whitespace does not include the VT character (code 11). In addition, characters between an unescaped “#” outside a character class and the next newline character, inclusive, are also ignored. This can be changed within a pattern by a “(?x)” option setting.
- \textit{U} = G\textunderscore{}REGEX\_UNGREEDY - Inverts the “greediness” of the quantifiers so that they are not greedy by default, but become greedy if followed by “?”. It can also be set by a “(?U)” option setting within the pattern.

\textbf{GRegex.new(pattern)}

Compiles regular expression pattern into a regular expression object whose internal representation is corresponding to the library used. The returned result then can be used by the methods, e.g. match, exec, etc. Regular expression objects are automatically garbage collected.

Since: 1.11.3

\textbf{Arguments}

\textbf{pattern}

A Perl-compatible regular expression pattern string

\textbf{Returns}

The compiled regular expression (a userdata object)

\textbf{Errors}
• A malformed pattern generates a Lua error

**GRegex.flags([table])**

Returns a table containing the numeric values of the constants defined by the regex library, with the keys being the (string) names of the constants. If the table argument is supplied then it is used as the output table, otherwise a new table is created. The constants contained in the returned table can then be used in most functions and methods where compilation flags or execution flags can be specified. They can also be used for comparing with return codes of some functions and methods for determining the reason of failure.

Since: 1.11.3

**Arguments**

**table (optional)**

A table for placing results into

**Returns**

A table filled with the results.

**GRegex.compile_flags([table])**

Returns a table containing the numeric values of the constants defined by the regex library for compile flags, with the keys being the (string) names of the constants. If the table argument is supplied then it is used as the output table, otherwise a new table is created.

Since: 1.11.3

**Arguments**

**table (optional)**

A table for placing results into

**Returns**

A table filled with the results.

**GRegex.match_flags([table])**

Returns a table containing the numeric values of the constants defined by the regex library for match flags, with the keys being the (string) names of the constants. If the table argument is supplied then it is used as the output table, otherwise a new table is created.

Since: 1.11.3
Arguments

*table (optional)*

A table for placing results into

Returns

A table filled with the results.

**GRegex.match(subject, pattern, [init], [cf], [ef])**

Searches for the first match of the regexp pattern in the string subject, starting from offset init, subject to flags cf and ef. The pattern is compiled each time this is called, unlike the class method *match* function.

Since: 1.11.3

Arguments

subject

Subject string to search

pattern

A Perl-compatible regular expression pattern string or GRegex object

init (optional)

start offset in the subject (can be negative)

cf (optional)

compilation flags (bitwise OR)

ef (optional)

match execution flags (bitwise OR)

Returns

On success, returns all substring matches ("captures"), in the order they appear in the pattern. false is returned for sub-patterns that did not participate in the match. If the pattern specified no captures then the whole matched substring is returned. On failure, returns nil.

**GRegex.find(subject, pattern, [init], [cf], [ef])**

Searches for the first match of the regexp pattern in the string subject, starting from offset init, subject to flags ef. The pattern is compiled each time this is called, unlike the class method *find* function.

Since: 1.11.3
Arguments

**subject**
Subject string to search

**pattern**
A Perl-compatible regular expression pattern string or GRegex object

**init (optional)**
start offset in the subject (can be negative)

**cf (optional)**
compilation flags (bitwise OR)

**ef (optional)**
match execution flags (bitwise OR)

Returns
On success, returns the start point of the match (a number), the end point of the match (a number), and all substring matches ("captures"), in the order they appear in the pattern. false is returned for sub-patterns that did not participate in the match. On failure, returns nil.

**GRegex.gmatch(subject, pattern, [init], [cf], [ef])**

Returns an iterator for repeated matching of the pattern patt in the string subj, subject to flags cf and ef. The function is intended for use in the generic for Lua construct. The pattern can be a string or a GRegex object previously compiled with GRegex.new().

Since: 1.11.3
match execution flags (bitwise OR)

Returns

The iterator function is called by Lua. On every iteration (that is, on every match), it returns all captures in the order they appear in the pattern (or the entire match if the pattern specified no captures). The iteration will continue till the subject fails to match.

GRegex.gsub(subject, pattern, [repl], [max], [cf], [ef])

Searches for all matches of the pattern in the string subject and replaces them according to the parameters repl and max. The pattern can be a string or a GRegex object previously compiled with GRegex.new().

Since: 1.11.3

For details see: https://rrthomas.github.io/lrexlib/manual.html#gsub

Arguments

subject
  Subject string to search

pattern
  A Perl-compatible regular expression pattern string or GRegex object

repl (optional)
  Substitution source string, function, table, false or nil

max (optional)
  Maximum number of matches to search for, or control function, or nil

cf (optional)
  Compilation flags (bitwise OR)

ef (optional)
  Match execution flags (bitwise OR)

Returns

On success, returns the subject string with the substitutions made, the number of matches found, and the number of substitutions made.

GRegex.split(subject, sep, [cf], [ef])

Splits a subject string subj into parts (sections). The sep parameter is a regular expression pattern representing separators between the sections. The function is intended for use in the generic for
Lua construct. The function returns an iterator for repeated matching of the pattern sep in the string subj, subject to flags cf and ef. The sep pattern can be a string or a GRegex object previously compiled with GRegex.new(). Unlike gmatch, there will always be at least one iteration pass, even if there are no matches in the subject.

Since: 1.11.3

**Arguments**

**subject**
Subject string to search

**sep**
A Perl-compatible regular expression pattern string or GRegex object

**cf (optional)**
compilation flags (bitwise OR)

**ef (optional)**
match execution flags (bitwise OR)

**Returns**

The iterator function is called by Lua. On every iteration, it returns a subject section (can be an empty string), followed by all captures in the order they appear in the sep pattern (or the entire match if the sep pattern specified no captures). If there is no match (this can occur only in the last iteration), then nothing is returned after the subject section. The iteration will continue till the end of the subject.

**GRegex.version()**

Returns a string containing the version of the used library.

Since: 1.11.3

**Returns**

The version string

**gregex:match(subject, [init], [ef])**

Searches for the first match of the regexp pattern in the string subject, starting from offset init, subject to flags ef.

Since: 1.11.3

**Arguments**
subject
Subject string to search

init (optional)
start offset in the subject (can be negative)

ef (optional)
match execution flags (bitwise OR)

Returns
On success, returns all substring matches (“captures”), in the order they appear in the pattern. false is returned for sub-patterns that did not participate in the match. If the pattern specified no captures then the whole matched substring is returned. nil is returned if the pattern did not match.

gregex:find(subject, [init], [ef])
Searches for the first match of the regexp pattern in the string subject, starting from offset init, subject to flags ef.

Since: 1.11.3

Arguments
subject
Subject string to search

init (optional)
start offset in the subject (can be negative)

ef (optional)
match execution flags (bitwise OR)

Returns
On success, returns the start point of the match (a number), the end point of the match (a number), and all substring matches (“captures”), in the order they appear in the pattern. false is returned for sub-patterns that did not participate in the match. On failure, returns nil.

gregex:exec(subject, [init], [ef])
Searches for the first match of the compiled GRegex object in the string subject, starting from offset init, subject to the execution match flags ef.

Since: 1.11.3

Arguments
subject

Subject string to search

init (optional)

start offset in the subject (can be negative)

ef (optional)

match execution flags (bitwise OR)

Returns

On success, returns the start point of the first match (a number), the end point of the first match (a number), and the offsets of substring matches (“captures” in Lua terminology) are returned as a third result, in a table. This table contains false in the positions where the corresponding sub-pattern did not participate in the match. On failure, returns nil. Example: If the whole match is at offsets 10,20 and substring matches are at offsets 12,14 and 16,19 then the function returns the following: 10, 20, { 12,14,16,19 }.

gregex:dfa_exec(subject, [init], [ef])

Matches a compiled regular expression GRegex object against a given subject string subj, using a DFA matching algorithm.

Since: 1.11.3

Arguments

subject

Subject string to search

init (optional)

start offset in the subject (can be negative)

ef (optional)

match execution flags (bitwise OR)

Returns

On success, returns the start point of the matches found (a number), a table containing the end points of the matches found, the longer matches first, and the number of matches found as the third return value. On failure, returns nil. Example: If there are 3 matches found starting at offset 10 and ending at offsets 15, 20 and 25 then the function returns the following: 10, { 25,20,15 }, 3

gregex:__tostring()

Returns a string containing debug information about the GRegex object.
Since: 1.11.3

**Returns**

The debug string
User Interface

Introduction

Wireshark can be logically separated into the backend (dissecting protocols, file loading and saving, capturing, etc.) and the frontend (the user interface).

The following frontends are currently maintained by the Wireshark development team:

- Wireshark, Qt based
- TShark, console based

This chapter is focused on the Wireshark frontend, and especially on the Qt interface.

The Qt Application Framework

Qt is a cross-platform application development framework. While we mainly use the core (QtCore) and user interface (QtWidgets) modules, it also supports a number of other modules for specialized application development, such as networking (QtNetwork) and web browsing (QtWebKit).

At the time of this writing (September 2016) most of the main Wireshark application has been ported to Qt. The sections below provide an overview of the application and tips for Qt development in our environment.

User Experience Considerations

When creating or modifying Wireshark try to make sure that it will work well on Windows, macOS, and Linux. See Human Interface Reference Documents for details. Additionally, try to keep the following in mind:

**Workflow.** Excessive navigation and gratuitous dialogs should be avoided or reduced. For example, compared to the legacy UI many alert dialogs have been replaced with status bar messages. Statistics dialogs are displayed immediately instead of requiring that options be specified.

**Discoverability and feedback.** Most users don’t like to read documentation and instead prefer to learn an application as they use it. Providing feedback increases your sense of control and awareness, and makes the application more enjoyable to use. Most of the Qt dialogs provide a “hint” area near the bottom which shows useful information. For example, the “Follow Stream” dialog shows the packet corresponding to the text under the mouse. The profile management dialog shows a clickable path to the current profile. The main welcome screen shows live interface traffic. Most dialogs have a context menu that shows keyboard shortcuts.
Qt Creator

Qt Creator is a full-featured IDE and user interface editor. It makes adding new UI features much easier. It doesn’t work well on Windows at the present time, so it’s recommended that you use it on macOS or Linux.

To edit and build Wireshark using Qt Creator, open the top-level `CMakeLists.txt` within Qt Creator. It should ask you to choose a build location. Do so. It should then ask you to run CMake. Fill in any desired build arguments (e.g. `-D CMAKE_BUILD_TYPE=Debug` or `-D ENABLE_CCACHE=ON`) and click the [Run CMake] button. When that completes select Build › Open Build and Run Kit Selector… and make sure `wireshark` is selected.

Note that Qt Creator uses output created by CMake’s “CodeBlocks” generator. If you run CMake outside of Qt Creator you should use the “CodeBlocks - Unix Makefiles” generator, otherwise Qt Creator will prompt you to re-run CMake.

Source Code Overview

Wireshark’s main entry point is in `ui/qt/main.cpp`. Command-line arguments are processed there and the main application class (`WiresharkApplication`) instance is created there along with the main window.

The main window along with the rest of the application resides in `ui/qt`. Due to its size the main window code is split into two modules, `main_window.cpp` and `main_window_slots.cpp`.

Most of the modules in `ui/qt` are dialogs. Although we follow Qt naming conventions for class names, we follow our own conventions by separating file name components with underscores. For example, ColoringRulesDialog is defined in `coloring_rules_dialog.cpp`, `coloring_rules_dialog.h`, and `coloring_rules_dialog.ui`.

General-purpose dialogs are subclasses of `QDialog`. Dialogs that rely on the current capture file can subclass `WiresharkDialog`, which provides methods and members that make it easier to access the capture file and to keep the dialog open when the capture file closes.

Coding Practices and Naming Conventions

Names

The code in `ui/qt` directory uses three APIs: Qt (which uses InterCapConvention), GLib (which uses underscore_convention), and the Wireshark API (which also uses underscore_convention). As a general rule Wireshark’s Qt code uses InterCapConvention for class names, interCapConvention for methods, and underscore_convention for variables, with a trailing underscore_ for member variables.
Dialogs

Dialogs that work with capture file information shouldn't close just because the capture file closes. Subclassing `WiresharkDialog` as described above can make it easier to persist across capture files.

When you create a window with a row of standard “OK” and “Close” buttons at the bottom using Qt Creator you will end up with a subclass of QDialog. This is fine for traditional modal dialogs, but many times the “dialog” needs to behave like a QWindow instead.

Modal dialogs should be constructed with `QDialog(parent)`. Modeless dialogs (windows) should be constructed with `QDialog(NULL, Qt::Window)`. Other combinations (particularly `QDialog(parent, Qt::Window)`) can lead to odd and inconsistent behavior. Again, subclassing `WiresharkDialog` will take care of this for you.

Most of the dialogs in ui/qt share many similarities, including method names, widget names, and behavior. Most dialogs should have the following, although it's not strictly required:

- An `updateWidgets()` method, which enables and disables widgets depending on the current state and constraints of the dialog. For example, the Coloring Rules dialog disables the `Save` button if the user has entered an invalid display filter.

- A `hintLabel()` widget subclassed from `QLabel` or `ElidedLabel`, placed just above the dialog button box. The hint label provides guidance and feedback to the user.

- A context menu (`ctx_menu_`) for additional actions not present in the button box.

- If the dialog box contains a `QTreeWidget` you might want to add your own `QTreeWidgetItem` subclass with the following methods:
  
  ```
  drawData()
  Draws column data with any needed formatting.
  
  colData()
  Returns the data for each column as a `QVariant`. Used for copying as CSV, YAML, etc.
  
  operator<()
  Allows sorting columns based on their raw data.
  ```

Strings

Wireshark's C code and GLib use UTF-8 encoded character arrays. Qt (specifically `QString`) uses UTF-16. You can convert a `char *` to a `QString` using simple assignment. You can convert a `QString` to a `const char *` using `qUtf8Printable`.

If you're using GLib string functions or plain old C character array idioms in Qt-only code you're probably doing something wrong, particularly if you're manually allocating and releasing memory. QStrings are generally much safer and easier to use. They also make translations easier.

If you need to pass strings between Qt and GLib you can use a number of convenience routines
which are defined in \texttt{ui/qt/qt_ui_utils.h}.

If you're calling a function that returns \texttt{wmem}-allocated memory it might make more sense to add a wrapper function to \texttt{qt_ui_utils} than to call \texttt{wmem_free} in your code.

**Mixing C and C++**

Sometimes we have to call C++ functions from one of Wireshark's C callbacks and pass C++ objects to or from C. Tap listeners are a common example. The C++ FAQ describes how to do this safely.

Tapping usually involves declaring static methods for callbacks, passing \texttt{this} as the tap data.

**Internationalization and Translation**

Qt provides a convenient method for translating text: \texttt{QObject::tr()}, usually available as \texttt{tr()}.

However, please avoid using \texttt{tr()} for static strings and define them in \texttt{*ui} files instead. \texttt{tr()} on manually created objects like \texttt{QMenu} are not automatically retranslated and must instead be manually translated using \texttt{changeEvent()} and \texttt{retranslateUi()}. See \texttt{summary_dialog.[ch]} for an example of this.

\begin{itemize}
  \item \textbf{NOTE} If your object life is short and your components are (re)created dynamically then it is ok to use \texttt{tr()}.
\end{itemize}

In most cases you should handle the \texttt{changeEvent} in order to catch \texttt{QEvent::LanguageChange}.

Qt makes translating the Wireshark UI into different languages easy. To add a new translation, do the following:

\begin{itemize}
  \item Add your translation (\texttt{ui/qt/wireshark_XX.ts}) to \texttt{ui/qt/CMakeLists.txt}
  \item (Recommended) Add a flag image for your language in \texttt{images/languages/XX.svg}. Update \texttt{image/languages/languages.qrc} accordingly.
  \item Run \texttt{update ui/qt -ts ui/qt/wireshark_XX.ts} to generate/update your translation file.
  \item Translate with Qt Linguist: \texttt{linguist ui/qt/wireshark_XX.ts}.
  \item Do a test build and make sure the generated \texttt{wireshark_XX.qm} binary file is included.
  \item Push your translation to Gerrit for review. See Contribute your changes for details.
\end{itemize}

Alternatively you can put your QM and flag files in the \texttt{languages} directory in the Wireshark user configuration directory (\texttt{$XDG_CONFIG_HOME/wireshark/languages/} or \texttt{$HOME/.wireshark/languages/} on UNIX).

For more information about Qt Linguist see its manual.

You can also manage translations online with Transifex.
Each week translations are automatically synchronized with the source code through the following steps:

- pull ts from Transifex
- lupdate ts file
- push and commit on Gerrit
- push ts on Transifex

**Colors And Themes**

Qt provides a number of colors via the `QPalette` class. Use this class when you need a standard color provided by the underlying operating system.

Wireshark uses an extended version of the Tango Color Palette for many interface elements that require custom colors. This includes the I/O graphs, sequence diagrams, and RTP streams. Please use this palette (defined in `tango_colors.h` and the `ColorUtils` class) if `QPalette` doesn't meet your needs.

Wireshark supports dark themes (aka “dark mode”) on some platforms. We leverage Qt's dark theme support when possible, but have implemented our own support and workarounds in some cases. You can ensure that your code includes proper dark theme support by doing the following:

- You can use a macOS-style template icon by creating a monochrome SVG document with “.template” appended to the name, e.g. `image/stock_icons/24x24/edit-find.template.svg`.
- Qt draws unvisited links `Qt::blue` no matter what. You can work around this by using `ColorUtils::themeLinkBrush()` and `ColorUtils::themeLinkStyle()`.
- You can catch dark and light mode changes by handling `QEvent::ApplicationPaletteChange`.

**Other Issues and Information**

The main window has many QActions which are shared with child widgets. See `ui/qt/proto_tree.cpp` for an example of this.

**GammaRay** lets you inspect the internals of a running Qt application similar to Spy++ on Windows.

**Human Interface Reference Documents**

Wireshark runs on a number of platforms, primarily Windows, macOS, and Linux. It should conform to the Windows, macOS, GNOME, and KDE human interface guidelines as much as possible. Unfortunately, creating a feature that works well across these platforms can sometimes be a juggling act since the human interface guidelines for each platform often contradict one another. If you run into trouble you can ask the wireshark-dev mailing list as well as the User Experience Stack Exchange listed below.
For further reference, see the following:

- Android Design: https://developer.android.com/design/. Wireshark doesn’t have a mobile frontend (not yet, at least) but there is still useful information here.
- KDE Human Interface Guidelines: https://hig.kde.org
- User Experience Stack Exchange: https://ux.stackexchange.com/
Wireshark Tests

The Wireshark sources include a collection of Python scripts that test the features of Wireshark, TShark, Dumpcap, and other programs that accompany Wireshark. These are located in the `test` directory of the Wireshark source tree.

The command line options of Wireshark and its companion command line tools are numerous. These tests help to ensure that we don’t introduce bugs as Wireshark grows and evolves.

Quick Start

The recommended steps to prepare for and to run tests:

- Install two Python packages, pytest: `pip install pytest pytest-xdist`
- Build programs (“wireshark”, “tshark”, etc.): `ninja`
- Build additional programs for the “unittests” suite: `ninja test-programs`
- Run tests in the build directory: `pytest`

Replace `ninja test-programs` by `make test-programs` as needed.

The test suite will attempt to test as much as possible and skip tests when its dependencies are not satisfied. For example, packet capture tests require a Loopback interface and capture privileges. To avoid capture tests, pass the `--disable-capture` option.

List available tests with `pytest --collectonly`. Enable verbose output with `pytest --verbose`. For more details, see Listing And Running Tests (pytest).

If for whatever reason `pytest` is too old or unavailable, you could use a more limited test runner, `test/test.py`. Use `test/test.py --help` to see all options. For more details, see Listing And Running Tests.

CMake currently runs `test/test.py` when the “test” target is built.

Test suite structure

The following sections describes how the test suite is organized.

Test Coverage And Availability

The testing framework can run programs and check their stdout, stderr, and exit codes. It cannot interact with the Wireshark UI. Tests cover capture, command line options, decryption, file format support and conversion, Lua scripting, and other functionality.

Available tests depend on the libraries with which Wireshark was built. For example, some
decryption tests depend on a minimum version of Libgcrypt and Lua tests depend on Lua.

Capture tests depend on the permissions of the user running the test script. We assume that the test user has capture permissions on Windows and macOS and capture tests are enabled by default on those platforms.

If a feature is unavailable, the test will be skipped. For example, if an old version of Libgcrypt is in use, then some decryption tests will be skipped while other tests can still run to completion.

Suites, Cases, and Tests

The test/test.py script uses Python's “unittest” module. Our tests are patterned after it, and individual tests are organized according to suites, cases, and individual tests. Suites correspond to python modules that match the pattern “suite_*.py”. Cases correspond to one or more classes in each module, and case class methods matching the pattern “test_*” correspond to individual tests. For example, the invalid capture filter test in the TShark capture command line options test case in the command line options suite has the ID “suite_clopts.case_tshark_capture_clopts.test_tshark_invalid_capfilter”.

pytest fixtures

A test has typically additional dependencies, like the path to an executable, the path to a capture file, a configuration directory, the availability of an optional library, and so on. The Python unittest library is quite limited in expressing test dependencies, these are typically specified on the class instance itself (self) or via globals.

pytest is a better test framework which has full parallelization support (test-level instead of just suite-level), provides nicer test reports, and allows modular fixtures. Ideally the test suite should fully switch to pytest, but in meantime a compatibility layer is provided via the “fixtures” module.

A fixture is a function decorated with @fixtures.fixture and can either call fixtures.skip("reason") to skip tests that depend on the fixture, or return/yield a value. Test functions (and other fixture functions) can receive the fixture value by using the name of the fixture function as function parameters. Common fixtures are available in fixtures_ws.py and includes cmd_tshark for the path to the tshark executable and capture_file for a factory function that produces the path to a capture file.

Each unittest test case must be decorated with @fixtures.uses_fixtures to ensure that unittest test classes can actually request fixture dependencies.

Listing And Running Tests

Tests can be run via the test/test.py Python script. To run all tests, either run test/test.py in the directory that contains the Wireshark executables (wireshark, tshark, etc.), or pass the executable path via the -p flag:
You can list tests by passing one or more complete or partial names to `tshark.py`. The `-l` flag lists tests. By default all tests are shown.

# List all tests
$ python3 test/test.py -l
$ python3 test/test.py -l all
$ python3 test/test.py --list
$ python3 test/test.py --list all

# List only tests containing "dumpcap"
$ python3 test/test.py -l dumpcap

# List all suites
$ python3 test/test.py --list-suites

# List all suites and cases
$ python3 test/test.py --list-cases

If one of the listing flags is not present, tests are run. If no names or all is supplied, all tests are run. Otherwise tests that match are run.

# Run all tests
$ python3 test/test.py
$ python3 test/test.py all

# Only run tests containing "dumpcap"
$ python3 test/test.py -l dumpcap

# Run the "clopts" suite
$ python3 test/test.py suite_clopts

Run `python3 test/test.py --help` for all available options.

**Listing And Running Tests (pytest)**

Tests can also be run with `pytest`. Advantages include finer test selection, full parallelism, nicer test execution summaries, better output in case of failures (containing the contents of variables) and the ability to open the PDB debugger on failing tests.

To get started, install pytest 3.0 or newer and `pytest-xdist`:
# Install required packages on Ubuntu 18.04 or Debian jessie-backports
$ sudo apt install python3-pytest python3-pytest-xdist

# Install required packages on other systems
$ pip install pytest pytest-xdist

Run pytest in the Wireshark build directory, Wireshark binaries are assumed to be present in the run subdirectory (or run\RelWithDebInfo on Windows).

# Run all tests
$ cd /path/to/wireshark/build
$ pytest

# Run all except capture tests
$ pytest --disable-capture

# Run all tests with "decryption" in its name
$ pytest -k decryption

# Run all tests with an explicit path to the Wireshark executables
$ pytest --program-path /path/to/wireshark/build/run

To list tests without actually executing them, use the --collect-only option:

# List all tests
$ pytest --collect-only

# List only tests containing both "dfilter" and "tvb"
$ pytest --collect-only -k "dfilter and tvb"

The test suite will fail tests when programs are missing. When only a subset of programs are built or when some programs are disabled, then the test suite can be instructed to skip instead of fail tests:

# Run tests when libpcap support is disabled (-DENABLE_PCAP=OFF)
$ pytest --skip-missing-programs dumpcap,rawshark

# Run tests and ignore all tests with missing program dependencies
$ pytest --skip-missing-programs all

To open a Python debugger (PDB) on failing tests, use the --pdb option and disable parallelism with the -n0 option:
# Run decryption tests sequentially and open a debugger on failing tests

```
$ pytest -n0 --pdb -k decryption
```

Note that with the option `--pdb`, stray processes are not killed on test failures since the `SubprocessTestCase.tearDown` method is not executed. This limitation might be addressed in the future.

## Adding Or Modifying Tests

Tests must be in a Python module whose name matches “suite_*.py”. The module must contain one or more subclasses of “SubprocessTestCase” or “unittest.TestCase”. “SubprocessTestCase” is recommended since it contains several convenience methods for running processes, checking output, and displaying error information. Each test case method whose name starts with “test_” constitutes an individual test.

Success or failure conditions can be signalled using the “unittest.assertXXX()” or “subprocesstest.assertXXX()” methods.

Test dependencies (such as programs, directories, or the environment variables) are injected through method parameters. Commonly used fixtures include `cmd_tshark` and `capture_file`. See also `pytest fixtures`.

The “subprocesstest” class contains the following methods for running processes. Stdout and stderr is written to “<test id>.log”:

**startProcess**
- Start a process without waiting for it to finish.

**runProcess**
- Start a process and wait for it to finish.

**assertRun**
- Start a process, wait for it to finish, and check its exit code.

All of the current tests run one or more of Wireshark’s suite of executables and either check their return code or their output. A simple example is “suite_clopts.case_basic_clopts.test_existing_file”, which reads a capture file using TShark and checks its exit code.
import subprocess
import fixtures

@fixtures.mark_usefixtures('test_env')
@fixtures.uses_fixtures
class case_basic_clopts(subprocess.SubprocessTestCase):
    def test_existing_file(self, cmd_tshark, capture_file):
        self.assertRun((cmd_tshark, '-r', capture_file('dhcp.pcap')))

Program output can be checked using SubprocessTestCase.grepOutput, SubprocessTestCase.countOutput or other unittest.assert* methods:

import subprocess
import fixtures

@fixtures.mark_usefixtures('test_env')
@fixtures.uses_fixtures
class case_decrypt_80211(subprocess.SubprocessTestCase):
    def test_80211_wpa_psk(self, cmd_tshark, capture_file):
        tshark_proc = self.assertRun((cmd_tshark,
            '-o', 'wlan.enable_decryption: TRUE',
            '-Tfields',
            '-e', 'http.request.uri',
            '-r', capture_file('wpa-Induction.pcap.gz'),
            '-Y', 'http',
        ))
        self.assertIn('favicon.ico', tshark_proc.stdout_str)

Tests can be run in parallel. This means that any files you create must be unique for each test. "subprocesses.test_filename_from_id" can be used to generate a filename based on the current test name. It also ensures that the file will be automatically removed after the test has run.
This Document’s License (GPL)

As with the original license and documentation distributed with Wireshark, this document is covered by the GNU General Public License (GNU GPL).

If you haven’t read the GPL before, please do so. It explains all the things that you are allowed to do with this code and documentation.

Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Library General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.
We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

GNU GENERAL PUBLIC LICENSE

TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.
You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

   a) You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.

   b) You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

   c) If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may copy and distribute the Program (or a work based on it,
under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

a) Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

b) Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

c) Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

5. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are
prohibited by law if you do not accept this License. Therefore, by
modifying or distributing the Program (or any work based on the
Program), you indicate your acceptance of this License to do so, and
all its terms and conditions for copying, distributing or modifying
the Program or works based on it.

6. Each time you redistribute the Program (or any work based on the
Program), the recipient automatically receives a license from the
original licensor to copy, distribute or modify the Program subject to
these terms and conditions. You may not impose any further
restrictions on the recipients' exercise of the rights granted herein.
You are not responsible for enforcing compliance by third parties to
this License.

7. If, as a consequence of a court judgment or allegation of patent
infringement or for any other reason (not limited to patent issues),
conditions are imposed on you (whether by court order, agreement or
otherwise) that contradict the conditions of this License, they do not
excuse you from the conditions of this License. If you cannot
distribute so as to satisfy simultaneously your obligations under this
License and any other pertinent obligations, then as a consequence you
may not distribute the Program at all. For example, if a patent
license would not permit royalty-free redistribution of the Program by
all those who receive copies directly or indirectly through you, then
the only way you could satisfy both it and this License would be to
refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under
any particular circumstance, the balance of the section is intended to
apply and the section as a whole is intended to apply in other
circumstances.

It is not the purpose of this section to induce you to infringe any
patents or other property right claims or to contest validity of any
such claims; this section has the sole purpose of protecting the
integrity of the free software distribution system, which is
implemented by public license practices. Many people have made
generous contributions to the wide range of software distributed
through that system in reliance on consistent application of that
system; it is up to the author/donor to decide if he or she is willing
to distribute software through any other system and a licensee cannot
impose that choice.

This section is intended to make thoroughly clear what is believed to
be a consequence of the rest of this License.

8. If the distribution and/or use of the Program is restricted in
certain countries either by patents or by copyrighted interfaces, the
original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

9. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

NO WARRANTY

11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.
How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

Gnomovision version 69, Copyright (C) year name of author
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type `show w'.
This is free software, and you are welcome to redistribute it under certain conditions; type `show c' for details.

The hypothetical commands `show w' and `show c' should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than `show w' and `show c'; they could even be mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your
school, if any, to sign a "copyright disclaimer" for the program, if
necessary. Here is a sample; alter the names:

Yoyodyne, Inc., hereby disclaims all copyright interest in the program
'Gnomovision' (which makes passes at compilers) written by James Hacker.

<signature of Ty Coon>, 1 April 1989
Ty Coon, President of Vice

This General Public License does not permit incorporating your program into
proprietary programs. If your program is a subroutine library, you may
consider it more useful to permit linking proprietary applications with the
library. If this is what you want to do, use the GNU Library General
Public License instead of this License.
